# *Introduction*

This book is about the representation theory of commutative local rings, specifically the study of maximal Cohen-Macaulay modules over Cohen-Macaulay local rings.

The guiding principle of representation theory, broadly speaking, is that we can understand an algebraic structure by studying the sets upon which it acts. Classically, this meant understanding finite groups by studying the vector spaces they act upon; the powerful tools of linear algebra can then be brought to bear, revealing information about the group that was otherwise hidden. In other branches of representation theory, such as the study of finite-dimensional associative algebras, sophisticated technical machinery has been built to investigate the properties of modules, and how restrictions on modules over a ring restrict the structure of the ring.

The representation theory of maximal Cohen-Macaulay modules began in the late 1970s and grew quickly, inspired by three other areas of algebra. Spectacular successes in the representation theory of finite-dimensional algebras during the 1960s and 70s set the standard for what one might hope for from a representation theory. In particular, this period saw: Gabriel's introduction of the representations of quivers and his theorem that a quiver has finite representation type if and only if it is a disjoint union of ADE Coxeter-Dynkin diagrams; Auslander's influential Queen Mary notes applying his work on functor categories to representation theory; Auslander and Reiten's foundational work on AR sequences; and key insights from the Kiev school, particularly Drozd, Nazarova, and Roĭter. All these advances

continued the work on finite representation type begun in the 1940s and 50s by Nakayama, Brauer, Thrall, and Jans. Secondly, the study of lattices over orders, a part of integral representation theory, blossomed in the late 1960s. Restricting attention to lattices rather than arbitrary modules allowed a rich theory to develop. In particular, the work of Drozd-Roĭter and Jacobinski around this time introduced the conditions we call “the Drozd-Roĭter conditions” classifying commutative orders with only a finite number of non-isomorphic indecomposable lattices. Finally, Hochster’s study of the homological conjectures emphasized the importance of the maximal Cohen-Macaulay condition (even for non-finitely generated modules). The equality of the geometric invariant of dimension with the arithmetic one of depth makes this class of modules easy to work with, simultaneously ensuring that they faithfully reflect the structure of the ring.

The main focus of this book is on the problem of classifying Cohen-Macaulay local rings having only a finite number of indecomposable maximal Cohen-Macaulay modules, that is, having *finite CM type*. Notice that we wrote “the problem,” rather than “the solution.” Indeed, there is no complete classification to date. There are many partial results, however, including complete classifications in dimensions zero and one, a characterization in dimension two under some mild assumptions, and a complete understanding of the hypersurface singularities with this property. The tools developed to obtain these classifications have many applications to other problems as well, in addition to their inherent beauty. In particular there are applications to the study of other representation types, including countable type and bounded type.

This is not the first book about the representation theory of Cohen-Macaulay modules over Cohen-Macaulay local rings. The text [Yos90] by Yoshino is a fantastic book and an invaluable resource, and has inspired us both on countless occasions. It has been the canonical reference for the subject for twenty years. In those years, however, there have been many advances. To give just two examples, we mention Huneke and Leuschke's elementary proof in 2002 of Auslander's theorem that finite CM type implies isolated singularity, and R. Wiegand's 2000 verification of Schreyer's conjecture that finite CM type ascends to and descends from the completion. These developments alone might justify a new exposition. Furthermore, there are many facets of the subject not covered in Yoshino's book, some of which we are qualified to describe. Thus this book might be considered simultaneously an updated edition of [Yos90], a companion volume, and an alternative.

In addition to telling the basic story of finite CM type, our choice of material is guided by a number of themes.

(i) For a homomorphism of local rings  $R \rightarrow S$ , which maximal Cohen-Macaulay modules over  $S$  “come from”  $R$  is a basic question. It is especially important when  $S = \widehat{R}$ , the completion of  $R$ , for then the Krull-Remak-Schmidt uniqueness theorem holds for direct-sum decompositions of  $\widehat{R}$ -modules.

(ii) The failure of the Krull-Remak-Schmidt theorem is often more interesting than its success. We can often quantify exactly how badly it fails.

(iii) A certain amount of non-commutativity can be useful even in pure commutative algebra. In particular, the endomorphism ring of a module, while technically a non-commutative ring, should be a standard object of consideration in commutative algebra.

(iv) An abstract, categorical point of view is not always a good thing in and of itself. We tend to be stubbornly concrete, emphasizing explicit constructions over universal properties.

The main material of the book is divided into 16 chapters, which can be thought of as grouped roughly into six groups. The first chapter contains some vital background information on the Krull-Remak-Schmidt theorem, which we view as a version of the Fundamental Theorem of Arithmetic for modules, and on the relationship between modules over a local ring  $R$  and over its completion  $\widehat{R}$ . Chapter 2 is devoted to an analysis of exactly how badly the Krull-Remak-Schmidt theorem can fail. Nothing here is specifically about Cohen-Macaulay rings or maximal Cohen-Macaulay modules.

Chapters 3 and 4 contain the classification theorems for Cohen-Macaulay local rings of finite CM type in dimensions zero and one. Here essentially everything is known. In particular Chapter 3 introduces an auxiliary representation-theoretic problem, the Artinian pair, which is then used in Chapter 4 to solve the problem of finite CM type over one-dimensional rings.

The two-dimensional Cohen-Macaulay local rings of finite CM type are at a focal point in our telling of the theory, with connections to algebraic geometry, invariant theory, group representations, solid geometry, representations of quivers, and other areas, by way of the *McKay correspondence*.

Chapter 5 sets the stage for this material, introducing (in arbitrary dimension) the necessary invariant theory and results of Auslander relating a ring of invariants to the associated skew group ring. These results are applied in Chapter 6 to show that two-dimensional rings of invariants have finite CM type. In particular this applies to the Kleinian singularities, also known as Du Val singularities, rational double points, or ADE hypersurface singularities. We also describe some aspects of the McKay correspondence, including the geometric results due to Artin and Verdier. Finally Chapter 7 gives the full classification of complete local two-dimensional  $\mathbb{C}$ -algebras of finite CM type. This chapter also includes Auslander's theorem mentioned earlier that finite CM type implies isolated singularity.

In dimensions higher than two, our understanding of finite CM type is imperfect. We do, however, understand the Gorenstein case more or less completely. By a result of Herzog, a complete Gorenstein local ring of finite CM type is a hypersurface ring; these are completely classified in the equicharacteristic case. This classification is detailed in Chapter 9, including the theorem of Buchweitz-Greuel-Schreyer which states that if a complete equicharacteristic hypersurface singularity over an algebraically closed field has finite CM type, then it is a simple singularity in the sense of Arnol'd. We also write down the matrix factorizations for the indecomposable MCM modules over the Kleinian singularities, from which the matrix factorizations in arbitrary dimension can be obtained. Our proof of the Buchweitz-Greuel-Schreyer result is by reduction to dimension two via the double branched cover construction and Knörrer's periodicity theorem. Chapter 8 contains these background results, after a brief presentation of

the theory of matrix factorizations.

Chapter 10 addresses the critical questions of ascent and descent of finite CM type along ring extensions, particularly between a Cohen-Macaulay local ring and its completion, as well as passage to a local ring with a larger residue field. This allows us to extend the classification theorem for hypersurface singularities of finite CM type to non-algebraically closed fields.

The next pair of chapters describe powerful tools in the study of maximal Cohen-Macaulay modules: MCM approximations and Auslander-Reiten sequences. We are not aware of another complete, concise and explicit treatment of Auslander and Buchweitz's theory of MCM approximations and hulls of finite injective dimension, which we believe deserves to be better known. The theory of Auslander-Reiten sequences and quivers, of course, is essential.

The last four chapters consider other representation types, namely countable and bounded CM type, and finite CM type in higher dimensions. Chapter 13 uses recent results of Burban and Drozd, based on a modification of the conductor-square construction, to prove Buchweitz-Greuel-Schreyer's classification of the hypersurface singularities of countable CM type. It also proves certain structural results for rings of countable CM type, due to Huneke and Leuschke. Chapter 14 contains a proof of the first Brauer-Thrall conjecture, that an excellent isolated singularity with bounded CM type necessarily has finite CM type. Our presentation follows the original proofs of Dieterich and Yoshino. The Brauer-Thrall theorem is then used, in Chapter 15, to prove that two three-dimensional examples have finite CM type. We also quote the theorem of Eisenbud and Herzog which classi-

fies the standard graded rings of finite CM type; in particular, their result says that there are no examples in dimension  $\geq 3$  other than the ones we have described in the text. Finally, in Chapter 16, we consider the rings of bounded but infinite CM type. It happens that for hypersurface rings they are precisely the same as the rings of countable but infinite CM type. We also classify the one-dimensional rings of bounded CM type.

We include two Appendices. In Appendix A, we gather for ease of reference some basic definitions and results of commutative algebra that are prerequisites for the book. Appendix B, on the other hand, contains material that we require from ramification theory that is not generally covered in a general commutative algebra course. It includes the basics on unramified and étale homomorphisms, Henselian rings, ramification of prime ideals, and purity of the branch locus. We make essential use of these concepts, but they are peripheral to the main material of the book.

The knowledgeable reader will have noticed significant overlap between the topics mentioned above and those covered by Yoshino in [Yos90]. To a certain extent this is unavoidable; the basics of the area are what they are, and any book on Cohen-Macaulay representation types will mention them. However, the reader should be aware that our guiding principles are quite different from Yoshino's, and consequently there are few topics on which our presentation parallels that in [Yos90]. When it does, it is generally because both books follow the original presentation of Auslander, Auslander-Reiten, or Yoshino.

Early versions of this book have been used for advanced graduate courses at the University of Nebraska in Fall 2007 and at Syracuse University in

Fall 2010. In each case, the students had had at least one full-semester course in commutative algebra at the level of Matsumura's book [Mat89]. A few more advanced topics are needed from time to time, such as the basics of group representations and character theory, properties of canonical modules and Gorenstein rings, Cohen's structure theory for complete local rings, the Artin-Rees Lemma, and the material on multiplicity and Serre's conditions in the Appendix. Many of these can be taken on faith at first encounter, or covered as extra topics.

The core of the book, Chapters 3 through 9, is already more material than could comfortably be covered in a semester course. One remedy would be to streamline the material, restricting to the case of complete local rings with algebraically closed residue fields of characteristic zero. One might also skip or sketch some of the more tangential material. We regard the following as essential: Chapter 3 (omitting most of the proof of Theorem 3.5); the first three sections of Chapter 4; Chapter 5; Chapter 6 (omitting the proof of Theorem 6.11, the calculations in §3, and §4); Chapters 7 and 8; and the first two sections of Chapter 9. Chapters 2 and 10 can each stand alone as optional topics, while the thread beginning with Chapters 11 and 12, continuing through Chapters 14 and 16 could serve as the basis of a completely separate course (though some knowledge of the first half of the book would be necessary to make sense of Chapters 13 and 15).

At the end of each chapter is a short section of exercises of varying difficulty, over 120 in all. Some are independent problems, while others ask the solver to fill in details of proofs omitted from the body of the text.

We gratefully acknowledge the many people and organizations whose

support we enjoyed while writing this book. Our students at Nebraska and Syracuse endured early drafts of the text, and helped us improve it; thanks to Tom Bleier, Jesse Burke, Ela Çelikbas, Olgur Çelikbas, Justin Devries, Kos Diveris, Christina Eubanks-Turner, Inês Bonacho dos Anjos Henriques, Nick Imnholte, Brian Johnson, Micah Leamer, Laura Lynch, Matt Mastroeni, Lori McDonnell, Sean Mead-Gluchacki, Livia Miller, Frank Moore, Terri Moore, Frank Moore, Hamid Rahmati, Silvia Saccon, and Mark Yerrington. GJL was supported by National Science Foundation grants DMS-0556181 and DMS-0902119 while working on this project, and RW by a grant from the National Security Agency. The CIRM at Luminy hosted us for a highly productive and enjoyable week in June 2010. Each of us visited the other several times over the years, and enjoyed the hospitality of each other's home department, for which we thank UNL and SU, respectively. Finally, . . . .

## *The Krull-Remak-Schmidt theorem*

In this chapter we will prove the Krull-Remak-Schmidt uniqueness theorem for direct-sum decompositions of finitely generated modules over complete local rings. The first such theorem, in the context of finite groups, was stated by J. H. M. Wedderburn [Wed09]: Let  $G$  be a finite group with two direct-product decompositions  $G = H_1 \times \cdots \times H_m$  and  $G = K_1 \times \cdots \times K_n$ , where each  $H_i$  and each  $K_j$  is indecomposable. Then  $m = n$ , and, after renumbering,  $H_i \cong K_i$  for each  $i$ . In 1911 Remak [Rem11] gave a complete proof, and actually proved more:  $H_i$  and  $K_i$  are *centrally isomorphic*, that is, there are isomorphisms  $f_i: H_i \rightarrow K_i$  such that  $x^{-1}f(x)$  is in the center of  $G$  for each  $x \in H_i$ ,  $i = 1, \dots, m$ . These results were extended to groups with operators satisfying the ascending and descending chain conditions by Krull [Kru25] and Schmidt [Sch29]. In 1950 Azumaya [Azu50] proved an analogous result for possibly infinite direct sums of modules, with the assumption that the endomorphism ring of each factor is local in the non-commutative sense.

### **§1 KRS in an additive category**

Looking ahead to an application in Chapter 3, we will clutter things up slightly by working in an additive category, rather than a category of modules. An *additive* category is a category  $\mathcal{A}$  with 0-object such that (i)  $\text{Hom}_{\mathcal{A}}(M_1, M_2)$  is an abelian group for each pair  $M_1, M_2$  of objects, (ii) composition is bilinear, and (iii) every finite set of objects has a biprod-

uct. A *biproduct* of  $M_1, \dots, M_m$  consists of an object  $M$  together with maps  $u_i: M_i \rightarrow M$  and  $p_i: M \rightarrow M_i$ ,  $i = 1, \dots, m$ , such that  $p_i u_j = \delta_{ij}$  and  $u_1 p_1 + \dots + u_m p_m = 1_M$ . We denote the biproduct by  $M_1 \oplus \dots \oplus M_m$ .

We will need an additional condition on our additive category, namely, that idempotents split (cf. [Bas68, Chapter I, §3, p. 19]). Given an object  $M$  and an idempotent  $e \in \text{End}_{\mathcal{A}}(M)$ , we say that  $e$  *splits* provided there is a factorization  $M \xrightarrow{p} K \xrightarrow{u} M$  such that  $e = up$  and  $pu = 1_K$ .

The reader is probably familiar with the notion of an *abelian* category, that is, an additive category in which every map has a kernel and a cokernel, and in which every monomorphism (respectively epimorphism) is a kernel (respectively cokernel). Over any ring  $R$  the category  $R\text{-Mod}$  of all left  $R$ -modules is abelian; if  $R$  is left Noetherian, then the category  $R\text{-mod}$  of finitely generated left  $R$ -modules is abelian. It is easy to see that idempotents split in an abelian category. Indeed, suppose  $e: M \rightarrow M$  is an idempotent, and let  $u: K \rightarrow M$  be the kernel of  $1_M - e$ . Since  $(1_M - e)e = 0$ , the map  $e$  factors through  $u$ ; that is, there is a map  $p: M \rightarrow K$  satisfying  $up = e$ . Then  $upu = eu = eu + (1_M - e)u = u = u1_K$ . Since  $u$  is a monomorphism (as kernels are always monomorphisms), it follows that  $pu = 1_K$ .

A non-zero object  $M$  in the additive category  $\mathcal{A}$  is said to be *decomposable* if there exist non-zero objects  $M_1$  and  $M_2$  such that  $M \cong M_1 \oplus M_2$ . Otherwise,  $M$  is *indecomposable*. We leave the proof of the next result as an exercise:

**1.1 Proposition.** *Let  $M$  be a non-zero object in an additive category  $\mathcal{A}$ , and let  $E = \text{End}_{\mathcal{A}}(M)$ .*

(i) *If 0 and 1 are the only idempotents of  $E$ , then  $M$  is indecomposable.*

(ii) Conversely, if  $e = e^2 \in E$ , if both  $e$  and  $1 - e$  split, and if  $e \neq 0, 1$ , then  $M$  is decomposable.

We say that the Krull-Remak-Schmidt Theorem (KRS for short) holds in the additive category  $\mathcal{A}$  provided

- (i) every object in  $\mathcal{A}$  is a biproduct of indecomposable objects, and
- (ii) if  $M_1 \oplus \cdots \oplus M_m \cong N_1 \oplus \cdots \oplus N_n$ , with each  $M_i$  and each  $N_j$  an indecomposable object in  $\mathcal{A}$ , then  $m = n$  and, after renumbering,  $M_i \cong N_i$  for each  $i$ .

It is easy to see that every Noetherian object is a biproduct of finitely many indecomposable objects (cf. Exercise 1.19), but there are easy examples to show that (ii) can fail. For perhaps the simplest example, let  $R = k[x, y]$ , the polynomial ring in two variables over a field. Letting  $\mathfrak{m} = Rx + Ry$  and  $\mathfrak{n} = R(x - 1) + Ry$ , we get a short exact sequence

$$0 \longrightarrow \mathfrak{m} \cap \mathfrak{n} \longrightarrow \mathfrak{m} \oplus \mathfrak{n} \longrightarrow R \longrightarrow 0,$$

since  $\mathfrak{m} + \mathfrak{n} = R$ . This splits, so  $\mathfrak{m} \oplus \mathfrak{n} \cong R \oplus (\mathfrak{m} \cap \mathfrak{n})$ . Since neither  $\mathfrak{m}$  nor  $\mathfrak{n}$  is isomorphic to  $R$  as an  $R$ -module, KRS fails for finitely generated  $R$ -modules.

Alternatively, let  $D$  be a Dedekind domain with a non-principal ideal  $I$ . We have an isomorphism (see Exercise 1.20)

$$(1.1.1) \quad R \oplus R \cong I \oplus I^{-1},$$

and of course all of the summands in (1.1.1) are indecomposable.

These examples indicate that KRS is likely to fail for modules over rings that aren't local. It can fail even for finitely generated modules over local rings. An example due to R. G. Swan is in E. G. Evans's paper [Eva73]. In Chapter 2 we will see just how badly it can fail. G. Azumaya [Azu48] observed that the crucial property for guaranteeing KRS is that the endomorphism rings of the summands be local in the non-commutative sense. To avoid a conflict of jargon, we define a ring  $\Lambda$  (not necessarily commutative) to be *nc-local* provided  $\Lambda/\mathcal{J}(\Lambda)$  is a division ring, where  $\mathcal{J}(-)$  denotes the Jacobson radical. Equivalently (cf. Exercise 1.21)  $\Lambda \neq \{0\}$  and  $\mathcal{J}(\Lambda)$  is exactly the set of non-units of  $\Lambda$ . It is clear from Proposition 1.1 that any object with nc-local endomorphism ring must be indecomposable.

We'll model our proof of KRS after the proof of unique factorization in the integers, by showing that an object with nc-local endomorphism ring behaves like a prime element in an integral domain. We'll even use the same notation, writing " $M \mid N$ ", for objects  $M$  and  $N$ , to indicate that there is an object  $Z$  such that  $N \cong M \oplus Z$ . Our inductive proof depends on direct-sum cancellation ((ii) below), analogous to the fact that  $mz = my \implies z = y$  for non-zero elements  $m, z, y$  in an integral domain. Later in the chapter (Corollary 1.16) we'll prove cancellation for arbitrary finitely generated modules over a local ring, but for now we'll prove only that objects with nc-local endomorphism rings can be cancelled.

**1.2 Lemma.** *Let  $\mathcal{A}$  be an additive category in which idempotents split. Let  $M, X, Y$ , and  $Z$  be objects of  $\mathcal{A}$ , let  $E = \text{End}_{\mathcal{A}}(M)$ , and assume that  $E$  is nc-local.*

(i) *If  $M \mid X \oplus Y$ , then  $M \mid X$  or  $M \mid Y$  ("primelike").*

(ii) If  $M \oplus Z \cong M \oplus Y$ , then  $Z \cong Y$  (“cancellation”).

*Proof.* We’ll prove (i) and (ii) sort of simultaneously. In (i) we have an object  $Z$  such that  $M \oplus Z \cong X \oplus Y$ . In the proof of (ii) we set  $X = M$  and again get an isomorphism  $M \oplus Z \cong X \oplus Y$ . Put  $J = \mathcal{J}(E)$ , the set of non-units of  $E$ .

Choose reciprocal isomorphisms  $\varphi: M \oplus Z \rightarrow X \oplus Y$  and  $\psi: X \oplus Y \rightarrow M \oplus Z$ . Write

$$\varphi = \begin{bmatrix} \alpha & \beta \\ \gamma & \delta \end{bmatrix} \quad \text{and} \quad \psi = \begin{bmatrix} \mu & \nu \\ \sigma & \tau \end{bmatrix},$$

where  $\alpha: M \rightarrow X, \beta: Z \rightarrow X, \gamma: M \rightarrow Y, \delta: Z \rightarrow Y, \mu: X \rightarrow M, \nu: Y \rightarrow M, \sigma: X \rightarrow Z$  and  $\tau: Y \rightarrow Z$ . Since  $\psi\varphi = 1_{M \oplus Z} = \begin{bmatrix} 1_M & 0 \\ 0 & 1_Z \end{bmatrix}$ , we have  $\mu\alpha + \nu\gamma = 1_M$ . Therefore, as  $E$  is local, either  $\mu\alpha$  or  $\nu\gamma$  must be outside  $J$  and hence an automorphism of  $M$ . Assuming that  $\mu\alpha$  is an automorphism, we will produce an object  $W$  and maps

$$M \xrightarrow{u} X \xrightarrow{p} M \quad W \xrightarrow{v} X \xrightarrow{q} W$$

satisfying  $pu = 1_M, pv = 0, qv = 1_W, qu = 0$ , and  $up + vq = 1_X$ . This will show that  $X = M \oplus W$ . (Similarly, the assumption that  $\nu\gamma$  is an isomorphism forces  $M$  to be a direct summand of  $Y$ .)

Letting  $u = \alpha, p = (\mu\alpha)^{-1}\mu$  and  $e = up \in \text{End}_{\mathcal{A}}(X)$ , we have  $pu = 1_M$  and  $e^2 = e$ . By hypothesis, the idempotent  $1 - e$  splits, so we can write  $1 - e = vq$ , where  $X \xrightarrow{q} W \xrightarrow{v} X$  and  $qv = 1_W$ . From  $e = up$  and  $1 - e = vq$ , we get the equation  $up + vq = 1_X$ . Moreover,  $qu = (qv)(qu)(pu) = q(vq)(up)u = q(1 - e)eu = 0$ ; similarly,  $pv = pupvqv = pe(1 - e)v = 0$ . We have verified all of the required equations, so  $X = M \oplus W$ . This proves (i).

To prove (ii) we assume that  $X = M$ . Suppose first that  $\alpha$  is a unit of  $E$ . We use  $\alpha$  to diagonalize  $\varphi$ :

$$\begin{bmatrix} 1 & 0 \\ -\gamma\alpha^{-1} & 1 \end{bmatrix} \begin{bmatrix} \alpha & \beta \\ \gamma & \delta \end{bmatrix} \begin{bmatrix} 1 & -\alpha^{-1}\beta \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} \alpha & 0 \\ 0 & -\gamma\alpha^{-1}\beta + \delta \end{bmatrix}$$

Since all the matrices on the left are invertible, so must be the one on the right, and it follows that  $-\gamma\alpha^{-1}\beta + \delta: Z \rightarrow Y$  is an isomorphism.

Suppose, on the other hand, that  $\alpha \in J$ . Then  $\nu\gamma \notin J$  (as  $\mu\alpha + \nu\gamma = 1_M$ ), and it follows that  $\alpha + \nu\gamma \notin J$ . We define a new map

$$\psi' = \begin{bmatrix} 1_M & \nu \\ \sigma & \tau \end{bmatrix} : M \oplus Y \rightarrow M \oplus Z,$$

which we claim is an isomorphism. Assuming the claim, we can diagonalize  $\psi'$  as we did  $\varphi$ , obtaining, in the lower-right corner, an isomorphism from  $Y$  onto  $Z$ , and finishing the proof. To prove the claim, we use the equation  $\psi\varphi = 1_{M \oplus Z}$  to get

$$\psi'\varphi = \begin{bmatrix} \alpha + \nu\gamma & \beta + \nu\gamma \\ 0 & 1_Z \end{bmatrix}.$$

As  $\alpha + \nu\gamma$  is an automorphism of  $M$ ,  $\psi'\varphi$  is clearly an automorphism of  $M \oplus Z$ . Therefore  $\psi' = (\psi'\varphi)\varphi^{-1}$  is an isomorphism.  $\square$

**1.3 Theorem** (Krull-Remak-Schmidt-Azumaya). *Let  $\mathcal{A}$  be an additive category in which every idempotent splits. Let  $M_1, \dots, M_m$  and  $N_1, \dots, N_n$  be indecomposable objects of  $\mathcal{A}$ , with  $M_1 \oplus \dots \oplus M_m \cong N_1 \oplus \dots \oplus N_n$ . Assume that  $\text{End}_{\mathcal{A}}(M_i)$  is  $nc$ -local for each  $i$ . Then  $m = n$  and, after renumbering,  $M_i \cong N_i$  for each  $i$ .*

*Proof.* We use induction on  $m$ , the case  $m = 1$  being trivial. Assuming  $m \geq 2$ , we see that  $M_m \mid N_1 \oplus \cdots \oplus N_n$ . By (i) of Lemma 1.2,  $M_m \mid N_j$  for some  $j$ ; by renumbering, we may assume that  $M_m \mid N_n$ . Since  $N_n$  is indecomposable and  $M_m \neq 0$ , we must have  $M_m \cong N_n$ . Now (ii) of Lemma 1.2 implies that  $M_1 \oplus \cdots \oplus M_{m-1} \cong N_1 \oplus \cdots \oplus N_{n-1}$ , and the inductive hypothesis completes the proof.  $\square$

Azumaya [Azu48] actually proved the *infinite* version of Theorem 1.3: If  $\bigoplus_{i \in I} M_i \cong \bigoplus_{j \in J} N_j$  and the endomorphism ring of each  $M_i$  is nc-local, and each  $N_j$  is indecomposable, then there is a bijection  $\sigma: I \rightarrow J$  such that  $M_i \cong N_{\sigma(i)}$  for each  $i$ . (Cf. [Fac98, Chapter 2].)

We want to find some situations where indecomposables automatically have nc-local endomorphism rings. It is well known that idempotents lift modulo any nil ideal. A typical proof of this fact actually yields the following stronger result, which we will use in the next section.

**1.4 Proposition.** *Let  $I$  be a two-sided ideal of a (possibly non-commutative) ring  $\Lambda$ , and let  $e$  be an idempotent of  $\Lambda/I$ . Given any positive integer  $n$ , there is an element  $x \in \Lambda$  such that  $x + I = e$  and  $x \equiv x^2 \pmod{I^n}$ .*

*Proof.* Start with an arbitrary element  $u \in \Lambda$  such that  $u + I = e$ , and let  $v = 1 - u$ . In the binomial expansion of  $(u + v)^{2n-1}$ , let  $x$  be the sum of the first  $n$  terms:  $x = u^{2n-1} + \cdots + \binom{2n-1}{n-1} u^n v^{n-1}$ . Putting  $y = 1 - x$  (the other half of the expansion), we see that  $x - x^2 = xy \in \Lambda(uv)^n \Lambda$ . Since  $uv = u(1 - u) \in I$ , we have  $x - x^2 \in I^n$ .  $\square$

Here is an easy consequence, which will be needed in Chapter 3:

**1.5 Corollary.** *Let  $M$  be an indecomposable object in an additive category  $\mathcal{A}$ . Assume that idempotents split in  $\mathcal{A}$ . If  $E := \text{End}_{\mathcal{A}}(M)$  is left or right Artinian, then  $E$  is nc-local.*

*Proof.* Since  $M$  is indecomposable,  $E$  has no non-trivial idempotents. Since  $\mathcal{J}(E)$  is nilpotent, Proposition 1.4 implies that  $E/\mathcal{J}(E)$  has no idempotents either. It follows easily from the Wedderburn-Artin Theorem [Lam91, (3.5)] that  $E/\mathcal{J}(E)$  is a division ring, whence nc-local.  $\square$

**1.6 Corollary.** *Let  $R$  be a commutative Artinian ring. Then KRS holds in the category of finitely generated  $R$ -modules.*

*Proof.* Let  $M$  be an indecomposable finitely generated  $R$ -module. By Exercise 1.22  $\text{End}_R(M)$  is finitely generated as an  $R$ -module and therefore is a left- (and right-) Artinian ring. Now apply Corollary 1.5 and Theorem 1.3.  $\square$

## §2 KRS over Henselian rings

We now proceed to prove KRS for finitely generated modules over complete and, more generally, Henselian local rings. Here we define a local ring  $(R, \mathfrak{m}, k)$  to be *Henselian* provided, for every module-finite  $R$ -algebra  $\Lambda$  (not necessarily commutative), each idempotent of  $\Lambda/\mathcal{J}(\Lambda)$  lifts to an idempotent of  $\Lambda$ . For the classical definition of “Henselian” in terms of factorization of polynomials, and for other equivalent conditions, see Theorem A.31.

**1.7 Lemma.** *Let  $R$  be a commutative ring and  $\Lambda$  a module-finite  $R$ -algebra (not necessarily commutative). Then  $\Lambda \mathcal{J}(R) \subseteq \mathcal{J}(\Lambda)$ .*

*Proof.* Let  $f \in \Lambda \setminus \mathcal{J}(R)$ . We want to show that  $\Lambda(1 - \lambda f) = \Lambda$  for every  $\lambda \in \Lambda$ . Clearly  $\Lambda(1 - \lambda f) + \Lambda \setminus \mathcal{J}(R) = \Lambda$ , and now NAK completes the proof.  $\square$

**1.8 Theorem.** *Let  $(R, \mathfrak{m}, k)$  be a Henselian local ring, and let  $M$  be an indecomposable finitely generated  $R$ -module. Then  $\text{End}_R(M)$  is nc-local. In particular, KRS holds for the category of finitely generated modules over a Henselian local ring.*

*Proof.* Let  $E = \text{End}_R(M)$  and  $J = \mathcal{J}(E)$ . Since  $E$  is a module-finite  $R$ -algebra (cf. Exercise 1.22), Lemma 1.7 implies that  $\mathfrak{m}E \subseteq J$  and hence that  $E/J$  is a finite-dimensional  $k$ -algebra. It follows that  $E/J$  is semisimple Artinian. Moreover, since  $E$  has no non-trivial idempotents, neither does  $E/J$ . By the Wedderburn-Artin Theorem [Lam91, (3.5)],  $E/J$  is a division ring.  $\square$

**1.9 Corollary** (Hensel's Lemma). *Every complete local ring is Henselian.*

*Proof.* Let  $(R, \mathfrak{m}, k)$  be a complete local ring, let  $\Lambda$  be a module-finite  $R$ -algebra, and put  $J = \mathcal{J}(\Lambda)$ . Again,  $\mathfrak{m}\Lambda \subseteq J$ , and  $J/\mathfrak{m}\Lambda$  is a nilpotent ideal of  $\Lambda/\mathfrak{m}\Lambda$  (since  $\Lambda/\mathfrak{m}\Lambda$  is Artinian). By Proposition 1.4 we can lift each idempotent of  $\Lambda/J$  to an idempotent of  $\Lambda/\mathfrak{m}\Lambda$ . Therefore it will suffice to show that every idempotent  $e$  of  $\Lambda/\mathfrak{m}\Lambda$  lifts to an idempotent of  $\Lambda$ . Using Proposition 1.4, we can choose, for each positive integer  $n$ , an element  $x_n \in \Lambda$  such that  $x_n + \mathfrak{m}\Lambda = e$  and  $x_n \equiv x_n^2 \pmod{\mathfrak{m}^n \Lambda}$ . (Of course  $\mathfrak{m}^n \Lambda = (\mathfrak{m}\Lambda)^n$ .) We claim that  $(x_n)$  is a Cauchy sequence for the  $\mathfrak{m}\Lambda$ -adic topology on  $\Lambda$ . To see this, let  $n$  be an arbitrary positive integer. Given any  $m \geq n$ , put  $z = x_m + x_n - 2x_m x_n$ . Then  $z \equiv z^2 \pmod{\mathfrak{m}^n \Lambda}$ . Also, since  $x_m \equiv x_n \pmod{\mathfrak{m}\Lambda}$ , we see that  $z \equiv 0 \pmod{\mathfrak{m}\Lambda}$ , so  $1 - z$  is a unit of  $\Lambda$ . Since  $z(1 - z) \in \mathfrak{m}^n \Lambda$ , it

follows that  $z \in \mathfrak{m}^n \Lambda$ . Thus we have

$$x_m + x_n \equiv 2x_m x_n, \quad x_m \equiv x_m^2, \quad x_n \equiv x_n^2 \pmod{\mathfrak{m}^n \Lambda}.$$

Multiplying the first congruence, in turn, by  $x_m$  and by  $x_n$ , we learn that  $x_m \equiv x_m x_n \equiv x_n \pmod{\mathfrak{m}^n \Lambda}$ . If, now,  $\ell \geq n$  and  $m \geq n$ , we see that  $x_\ell \equiv x_m \pmod{\mathfrak{m}^n \Lambda}$ . This verifies the claim. Since  $\Lambda$  is  $\mathfrak{m}\Lambda$ -adically complete (cf. Exercise 1.24), we let  $x$  be the limit of the sequence  $(x_n)$  and check that  $x$  is an idempotent lifting  $e$ .  $\square$

**1.10 Corollary.** *KRS holds for finitely generated modules over complete local rings.*

Henselian rings are *almost* characterized by the Krull-Remak-Schmidt property. Indeed, a theorem due to E. G. Evans [Eva73] states that a local ring  $R$  is Henselian if and only if for every module-finite commutative local  $R$ -algebra  $A$  the finitely generated  $A$ -modules satisfy KRS.

### §3 $R$ -modules vs. $\widehat{R}$ -modules

A major theme in this book is the study of direct-sum decompositions over local rings that are not necessarily complete. Here we record a few results that will allow us to use KRS over  $\widehat{R}$  to understand  $R$ -modules.

We begin with a result due to Guralnick [Gur85] on lifting homomorphisms modulo high powers of the maximal ideal of a local ring. Given finitely generated modules  $M$  and  $N$  over a local ring  $(R, \mathfrak{m})$ , we define a *lifting number* for the pair  $(M, N)$  to be a non-negative integer  $e$  satisfying the following property: For each positive integer  $f$  and each  $R$ -homomorphism

$\xi: M/\mathfrak{m}^{e+f}M \rightarrow N/\mathfrak{m}^{e+f}N$ , there exists  $\sigma \in \text{Hom}_R(M, N)$  such that  $\sigma$  and  $\xi$  induce the same homomorphism  $M/\mathfrak{m}^fM \rightarrow N/\mathfrak{m}^fN$ . (Thus the outer and bottom squares in the diagram below both commute, though the top square may not.)

$$\begin{array}{ccc}
 M & \xrightarrow{\sigma} & N \\
 \downarrow & & \downarrow \\
 M/\mathfrak{m}^{e+f}M & \xrightarrow{\xi} & N/\mathfrak{m}^{e+f}N \\
 \downarrow & & \downarrow \\
 M/\mathfrak{m}^fM & \xrightarrow{\bar{\xi}=\bar{\sigma}} & N/\mathfrak{m}^fN
 \end{array}$$

For example, 0 is a lifting number for  $(M, N)$  if  $M$  is projective. Lemma 1.12 below shows that every pair of finitely generated modules has a lifting number.

**1.11 Lemma.** *If  $e$  is a lifting number for  $(M, N)$  and  $e' \geq e$ , then  $e'$  is also a lifting number for  $(M, N)$ .*

*Proof.* Let  $f'$  be a positive integer, and let  $\xi: M/\mathfrak{m}^{e'+f'}M \rightarrow N/\mathfrak{m}^{e'+f'}N$  be an  $R$ -homomorphism. Put  $f = f' + e' - e$ . Since  $e' + f' = e + f$  and  $e$  is a lifting number, there is a homomorphism  $\sigma: M \rightarrow N$  such that  $\sigma$  and  $\xi$  induce the same homomorphism  $M/\mathfrak{m}^fM \rightarrow N/\mathfrak{m}^fN$ . Now  $f \geq f'$ , and it follows that  $\sigma$  and  $\xi$  induce the same homomorphism  $M/\mathfrak{m}^{f'}M \rightarrow N/\mathfrak{m}^{f'}N$ .  $\square$

**1.12 Lemma** ([Gur85, Theorem A]). *Every pair  $(M, N)$  of modules over a local ring  $(R, \mathfrak{m})$  has a lifting number.*

*Proof.* Choose exact sequences

$$\begin{array}{l}
 F_1 \xrightarrow{\alpha} F_0 \rightarrow M \rightarrow 0, \\
 G_1 \xrightarrow{\beta} G_0 \rightarrow N \rightarrow 0,
 \end{array}$$

where  $F_i$  and  $G_i$  are finite-rank free  $R$ -modules. Define an  $R$ -homomorphism  $\Phi: \text{Hom}_R(F_0, G_0) \times \text{Hom}_R(F_1, G_1) \rightarrow \text{Hom}_R(F_1, G_0)$  by  $\Phi(\mu, \nu) = \mu\alpha - \beta\nu$ . Applying the Artin-Rees Lemma to the submodule  $\text{im}(\Phi)$  of  $\text{Hom}_R(F_1, G_0)$ , we get a positive integer  $e$  such that

$$(1.12.1) \quad \text{im}(\Phi) \cap \mathfrak{m}^{e+f} \text{Hom}_R(F_1, G_0) \subseteq \mathfrak{m}^f \text{im}(\Phi) \quad \text{for each } f > 0.$$

Suppose now that  $f > 0$  and  $\xi: M/\mathfrak{m}^{e+f}M \rightarrow N/\mathfrak{m}^{e+f}N$  is an  $R$ -homomorphism. We can lift  $\xi$  to homomorphisms  $\bar{\mu}_0$  and  $\bar{\nu}_0$  making the following diagram commute.

$$(1.12.2) \quad \begin{array}{ccccccc} F_1/\mathfrak{m}^{e+f}F_1 & \xrightarrow{\bar{\alpha}} & F_0/\mathfrak{m}^{e+f}F_0 & \longrightarrow & M/\mathfrak{m}^{e+f}M & \longrightarrow & 0 \\ \bar{\nu}_0 \downarrow & & \bar{\mu}_0 \downarrow & & \downarrow \xi & & \\ G_1/\mathfrak{m}^{e+f}G_1 & \xrightarrow{\bar{\beta}} & G_0/\mathfrak{m}^{e+f}G_0 & \longrightarrow & N/\mathfrak{m}^{e+f}N & \longrightarrow & 0 \end{array}$$

Now lift  $\bar{\mu}_0$  and  $\bar{\nu}_0$  to maps  $\mu_0 \in \text{Hom}_R(F_0, G_0)$  and  $\nu_0 \in \text{Hom}_R(F_1, G_1)$ . The commutativity of (1.12.2) implies that the image of  $\Phi(\mu_0, \nu_0): F_1 \rightarrow G_0$  lies in  $\mathfrak{m}^{e+f}G_0$ . Choosing bases for  $F_1$  and  $G_0$ , we see that the matrix representing  $\Phi(\mu_0, \nu_0)$  has entries in  $\mathfrak{m}^{e+f}$ , so that  $\Phi(\mu_0, \nu_0) \in \mathfrak{m}^{e+f} \text{Hom}_R(F_1, G_0)$ . By (1.12.1),  $\Phi(\mu_0, \nu_0) \in \mathfrak{m}^f \text{im}(\Phi) = \Phi(\mathfrak{m}^f (\text{Hom}_R(F_0, G_0) \times \text{Hom}_R(F_1, G_1)))$ . Choose  $(\mu_1, \nu_1) \in \mathfrak{m}^f (\text{Hom}_R(F_0, G_0) \times \text{Hom}_R(F_1, G_1))$  such that  $\Phi(\mu_1, \nu_1) = \Phi(\mu_0, \nu_0)$ , and set  $(\mu, \nu) = (\mu_0, \nu_0) - (\mu_1, \nu_1)$ . Then  $\Phi(\mu, \nu) = 0$ , so  $\mu$  induces an  $R$ -homomorphism  $\sigma: M \rightarrow N$ . Since  $\mu$  and  $\mu_0$  agree modulo  $\mathfrak{m}^f$ , it follows that  $\sigma$  and  $\xi$  induce the same map  $M/\mathfrak{m}^fM \rightarrow N/\mathfrak{m}^fN$ .  $\square$

We denote by  $e(M, N)$  the smallest lifting number for the pair  $(M, N)$ .

**1.13 Theorem** ([Gur85, Corollary 2]). *Let  $(R, \mathfrak{m})$  be a local ring, and let  $M$  and  $N$  be finitely generated  $R$ -modules. If  $r \geq \max\{e(M, N), e(N, M)\}$  and  $M/\mathfrak{m}^{r+1}M \mid N/\mathfrak{m}^{r+1}N$ , then  $M \mid N$ .*

*Proof.* Choose  $R$ -module homomorphisms  $\xi: M/\mathfrak{m}^{r+1}M \rightarrow N/\mathfrak{m}^{r+1}N$  and  $\eta: N/\mathfrak{m}^{r+1}N \rightarrow M/\mathfrak{m}^{r+1}M$  such that  $\eta\xi = 1_{M/\mathfrak{m}^{r+1}M}$ . Since  $r$  is a lifting number (Lemma 1.11), there exist  $R$ -homomorphisms  $\sigma: M \rightarrow N$  and  $\tau: N \rightarrow M$  such that  $\sigma$  agrees with  $\xi$  modulo  $\mathfrak{m}$  and  $\tau$  agrees with  $\eta$  modulo  $\mathfrak{m}$ . By Nakayama's lemma,  $\tau\sigma: M \rightarrow M$  is surjective and therefore, by Exercise 1.27, an automorphism. It follows that  $M \mid N$ .  $\square$

**1.14 Corollary.** *Let  $(R, \mathfrak{m})$  be a local ring and  $M, N$  finitely generated  $R$ -modules. If  $M/\mathfrak{m}^n M \cong N/\mathfrak{m}^n N$  for all  $n \gg 0$ , then  $M \cong N$ .*

*Proof.* By Theorem 1.13,  $M \mid N$  and  $N \mid M$ . In particular, we have surjections  $N \xrightarrow{\alpha} M$  and  $M \xrightarrow{\beta} N$ . Then  $\beta\alpha$  is a surjective endomorphism of  $N$  and therefore is an automorphism (cf. Exercise 1.27). It follows that  $\alpha$  is one-to-one and therefore an isomorphism.  $\square$

**1.15 Corollary.** *Let  $(R, \mathfrak{m})$  be a local ring and  $(\widehat{R}, \widehat{\mathfrak{m}})$  its  $\mathfrak{m}$ -adic completion. Let  $M$  and  $N$  be finitely generated  $R$ -modules.*

(i) *If  $\widehat{R} \otimes_R M \mid \widehat{R} \otimes_R N$ , then  $M \mid N$ .*

(ii) *If  $\widehat{R} \otimes_R M \cong \widehat{R} \otimes_R N$ , then  $M \cong N$ .*  $\square$

**1.16 Corollary.** *Let  $M, N$  and  $P$  be finitely generated modules over a local ring  $(R, \mathfrak{m})$ . If  $M \oplus P \cong N \oplus P$ , then  $M \cong N$ .*

*Proof.* We have  $(\widehat{R} \otimes_R M) \oplus (\widehat{R} \otimes_R P) \cong (\widehat{R} \otimes_R N) \oplus (\widehat{R} \otimes_R P)$ . Using KRS for complete rings (Corollary 1.9) we see easily that  $\widehat{R} \otimes_R M \cong \widehat{R} \otimes_R N$ . Now apply Corollary 1.15.  $\square$

## §4 Exercises

**1.17 Exercise.** Prove Proposition 1.1: For a non-zero object  $M$  in an additive category  $\mathcal{A}$ , and  $E = \text{End}_{\mathcal{A}}(M)$ , if 0 and 1 are the only idempotents of  $E$ , then  $M$  is indecomposable. Conversely, if  $e = e^2 \in E$ , if both  $e$  and  $1 - e$  split, and if  $e \neq 0, 1$ , then  $M$  is decomposable.

**1.18 Exercise.** Let  $M$  be an object in an additive category. Show that every direct-sum (i.e., coproduct) decomposition  $M = M_1 \oplus M_2$  has a biproduct structure.

**1.19 Exercise.** Let  $M$  be an object in an additive category.

- (i) Suppose that  $M$  has either the ascending chain condition or the descending chain condition on direct summands. Prove that  $M$  has an indecomposable direct summand.
- (ii) Prove that  $M$  is a direct sum (biproduct) of finitely many indecomposable objects.

**1.20 Exercise.** Prove Steinitz's Theorem ([Ste11]): Let  $I$  and  $J$  be non-zero fractional ideals of a Dedekind domain  $D$ . Then  $I \oplus J \cong D \oplus IJ$ .

**1.21 Exercise.** Let  $\Lambda$  be a ring with  $1 \neq 0$ . Prove that the following conditions are equivalent:

- (i)  $\Lambda$  is nc-local.
- (ii)  $\mathcal{J}(\Lambda)$  is the set of non-units of  $\Lambda$ .
- (iii) The set of non-units of  $\Lambda$  is closed under addition.

(Warning: In a non-commutative ring one can have non-units  $x$  and  $y$  such that  $xy = 1$ .)

**1.22 Exercise.** Let  $M$  and  $N$  be finitely generated modules over a commutative Noetherian ring  $R$ . Prove that  $\text{Hom}_R(M, N)$  is finitely generated as an  $R$ -module.

**1.23 Exercise.** Let  $(R, \mathfrak{m})$  be a Henselian local ring and  $X, Y, M$  finitely generated  $R$ -modules. Let  $\alpha: X \rightarrow M$  and  $\beta: Y \rightarrow M$  be homomorphisms which are not split surjections. Prove that  $[\alpha \ \beta]: X \oplus Y \rightarrow M$  is not a split surjection.

**1.24 Exercise.** Let  $M$  be a finitely generated module over a complete local ring  $(R, \mathfrak{m})$ . Show that  $M$  is complete for the topology defined by the submodules  $\mathfrak{m}^n M, n \geq 1$ .

**1.25 Exercise.** Prove Fitting's Lemma: Let  $\Lambda$  be any ring and  $M$  a  $\Lambda$ -module of finite length  $n$ . If  $f \in \text{End}_\Lambda(M)$ , then  $M = \ker(f^n) \oplus f^n(M)$ . Conclude that if  $M$  is indecomposable then every non-invertible element of  $\text{End}_\Lambda(M)$  is nilpotent.

**1.26 Exercise.** Use Exercise 1.21 and Fitting's Lemma (Exercise 1.25) to prove that the endomorphism ring of any indecomposable finite-length module is nc-local. Thus, over any ring  $R$ , KRS holds for the category of left  $R$ -modules of finite length. (Be careful: You're in a non-commutative setting, where the sum of two nilpotents might be a unit! If you get stuck, consult [Fac98, Lemma 2.21].)

**1.27 Exercise.** Let  $M$  be a Noetherian left  $\Lambda$ -module, and let  $f \in \text{End}_\Lambda(M)$ .

- (i) If  $f$  is surjective, prove that  $f$  is an automorphism of  $M$ . (Consider the ascending chain of submodules  $\ker(f^n)$ .)
- (ii) If  $f$  is surjective and  $f^2 = f$ , prove that  $f = 1_M$ .

## *Semigroups of modules*

In this chapter we analyze the different ways in which a finitely generated module over a local ring can be decomposed as a direct sum of indecomposable modules. Put another way, we are interested in exactly how badly KRS uniqueness can fail.

Our main result depends on a technical lemma, which provides indecomposable modules of varying ranks at the minimal prime ideals of a certain one-dimensional local ring. The proof of this lemma is left as an exercise, with hints directed at a similar argument in the the next chapter.

Given a ring  $A$ , choose a set  $V(A)$  of representatives for the isomorphism classes  $[M]$  of finitely generated left  $A$ -modules. We make  $V(A)$  into an additive semigroup in the obvious way:  $[M]+[N] = [M\oplus N]$ . This monoid encodes information about the direct-sum decompositions of finitely generated  $A$ -modules. (In what follows, we use the terms “semigroup” and “monoid” interchangeably.)

**2.1 Definition.** For a finitely generated left  $A$ -module  $M$ , we denote by  $\text{add}(M)$  the full subcategory of  $A\text{-mod}$  consisting of finitely generated modules that are isomorphic to direct summands of direct sums of copies of  $M$ . Also,  $+(M)$  is the subsemigroup of  $V(A)$  consisting of representatives of the isomorphism classes in  $\text{add}(M)$ .

In the special case where  $R$  is a complete local ring, it follows from KRS (Corollary 1.9) that  $V(R)$  is a *free monoid*, that is,  $V(R) \cong \mathbb{N}_0^{(I)}$ , where  $\mathbb{N}_0$  is the additive semigroup of non-negative integers and the index set  $I$  is

the set of atoms of  $V(R)$ , that is, the set of representatives for the indecomposable finitely generated  $R$ -modules. Furthermore, if  $M$  is a finitely generated  $R$ -module, then  $+(M)$  is free as well.

For a general local ring  $R$ , the semigroup  $V(R)$  is naturally a subsemigroup of  $V(\widehat{R})$  by Corollary 1.15, and similarly  $+(M)$  is a subsemigroup of  $+(\widehat{M})$  for an  $R$ -module  $M$ . This forces various structural restrictions on which semigroups can arise as  $V(R)$  for a local ring  $R$ , or as  $+(M)$  for a finitely generated  $R$ -module  $M$ . In short,  $+(M)$  must be a *finitely generated monoid*. In §1 we detail these restrictions, and in the rest of the chapter we prove two realization theorems, which show that every finitely generated Krull monoid can be realized in the form  $+(M)$  for a suitable local ring  $R$  and MCM  $R$ -module  $M$ . Both these theorems actually realize a semigroup  $\Lambda$  together with a given embedding  $\Lambda \subseteq \mathbb{N}_0^{(n)}$ . The first construction (Theorem 2.12) gives a one-dimensional domain  $R$  and a finitely generated torsion-free module  $M$  realizing an *expanded* subsemigroup  $\Lambda$  as  $+(M)$ , while the second (Theorem 2.17) gives a two-dimensional unique factorization domain  $R$  and a finitely generated reflexive module  $M$  realizing  $\Lambda$  as  $+(M)$ , assuming only that  $\Lambda$  is a *full* subsemigroup of  $\mathbb{N}_0^{(t)}$ . (See Proposition 2.4 for the terminology.)

## §1 Krull monoids

In this section, let  $(R, \mathfrak{m}, k)$  be a local ring with completion  $(\widehat{R}, \widehat{\mathfrak{m}}, k)$ . Let  $V(R)$  and  $V(\widehat{R})$  denote the semigroups, with respect to direct sum, of finitely generated modules over  $R$  and  $\widehat{R}$ , respectively. We write all our semigroups

additively, though we will keep the “multiplicative” notation inspired by direct sums,  $x \mid y$ , meaning that there exists  $z$  such that  $x + z = y$ . We write  $0$  for the neutral element  $[0]$  corresponding to the zero module.

There is a natural homomorphism of semigroups

$$j: V(R) \longrightarrow V(\widehat{R})$$

taking  $[M]$  to  $[\widehat{R} \otimes_R M]$ . This homomorphism is injective by Corollary 1.15, so we consider  $V(R)$  as a subsemigroup of  $V(\widehat{R})$ . It follows that  $V(R)$  is *cancellative*: if  $x + z = y + z$  for  $x, y, z \in V(R)$ , then  $x = y$ . Since in this chapter we will deal only with local rings, all of our semigroups will be tacitly assumed to be cancellative. We also see that  $V(R)$  is *reduced*, i.e.  $x + y = 0$  implies  $x = y = 0$ .

The homomorphism  $j: V(R) \longrightarrow V(\widehat{R})$  actually satisfies a much stronger condition than injectivity. A *divisor homomorphism* is a semigroup homomorphism  $j: \Lambda \longrightarrow \Lambda'$  such that  $j(x) \mid j(y)$  implies  $x \mid y$  for all  $x$  and  $y$  in  $\Lambda$ . Corollary 1.15 says that  $j: V(R) \longrightarrow V(\widehat{R})$  is a divisor homomorphism. Similarly, if  $M$  is a finitely generated  $R$ -module, the map  $+(M) \hookrightarrow +(\widehat{M})$  is a divisor homomorphism. A reassuring consequence is that a finitely generated module over a local ring has only finitely many direct-sum decompositions. (Cf. (1.1.1), which shows that this fails over a Dedekind domain with infinite class group.) To be precise, let us say that two direct-sum decompositions  $M \cong M_1 \oplus \cdots \oplus M_m$  and  $M \cong N_1 \oplus \cdots \oplus N_n$  are *equivalent* provided  $m = n$  and, after a permutation,  $M_i \cong N_i$  for each  $i$ . (We do not require that the summands be indecomposable.) The next theorem appears as Theorem 1.1 in [Wie99], with a slightly non-commutative proof. We will give a commutative proof here.

**2.2 Theorem.** *Let  $(R, \mathfrak{m})$  be a local ring, and let  $M$  be a finitely generated  $R$ -module. Then there are only finitely many isomorphism classes of indecomposable modules in  $\text{add}(M)$ . In particular,  $M$  has, up to equivalence, only finitely many direct sum decompositions.*

*Proof.* Let  $\widehat{R}$  be the  $\mathfrak{m}$ -adic completion of  $R$ , and write  $\widehat{R} \otimes_R M = V_1^{(n_1)} \oplus \cdots \oplus V_t^{(n_t)}$ , where each  $V_i$  is an indecomposable  $\widehat{R}$ -module and each  $n_i > 0$ . If  $L \in \text{add}(M)$ , then  $\widehat{R} \otimes_R L \cong V_1^{(a_1)} \oplus \cdots \oplus V_t^{(a_t)}$  for suitable non-negative integers  $a_i$ ; moreover, the integers  $a_i$  are uniquely determined by the isomorphism class  $[L]$ , by Corollary 1.9. Thus we have a well-defined map  $j: +(M) \rightarrow \mathbb{N}_0^t$ , taking  $[L]$  to  $(a_1, \dots, a_t)$ . Moreover, this map is one-to-one, by faithfully flat descent (Corollary 1.15).

If  $[L] \in +(M)$  and  $j([L])$  is a minimal non-zero element of  $j(+(M))$ , then  $L$  is clearly indecomposable. Conversely, if  $[L] \in \text{add}(M)$  and  $L$  is indecomposable, we claim that  $j([L])$  is a minimal non-zero element of  $j(+(M))$ . For, suppose that  $j([X]) < j([L])$ , where  $[X] \in +(M)$  is non-zero. Then  $\widehat{R} \otimes_R X \mid \widehat{R} \otimes_R L$ , so  $X \mid L$  by Corollary 1.15. But  $X \neq 0$  and  $X \not\cong L$  (else  $j([X]) = j([L])$ ), and we have a contradiction to the indecomposability of  $L$ .

By Dickson's Lemma (Exercise 2.21),  $j(+(M))$  has only finitely many minimal non-zero elements, and, by what we have just shown,  $\text{add}(M)$  has only finitely many isomorphism classes of indecomposable modules.

For the last statement, let  $n = \mu_R(M)$ , the number of elements in a minimal generating set for  $M$ , and let  $\{N_1, \dots, N_t\}$  be a complete set of representatives for the isomorphism classes of direct summands of  $M$ . Any direct summand of  $M$  is isomorphic to  $N_1^{(r_1)} \oplus \cdots \oplus N_t^{(r_t)}$ , where each  $r_i$  is non-negative and  $r_1 + \cdots + r_t \leq n$ . It follows that there are, up to isomorphism,

only finitely many direct summands of  $M$ . Let  $\{L_1, \dots, L_s\}$  be a set of representatives for the non-zero direct summands of  $M$ . Any direct-sum decomposition of  $M$  must have the form  $M \cong L_1^{(u_1)} \oplus \dots \oplus L_s^{(u_s)}$ , with  $u_1 + \dots + u_s \leq n$ , and it follows that there are only finitely many such decompositions.  $\square$

We will see in Example 2.13 that  $\text{add}(M)$  may contain indecomposable modules that do not occur as direct summands of  $M$ .

**2.3 Definition.** A *Krull monoid* is a monoid that admits a divisor homomorphism into a free monoid.

Every finitely generated Krull monoid admits a divisor homomorphism into  $\mathbb{N}_0^{(t)}$  for some positive integer  $t$ . Conversely, it follows easily from Dickson's Lemma (Exercise 2.21) that a monoid admitting a divisor homomorphism to  $\mathbb{N}_0^{(t)}$  must be finitely generated.

Finitely generated Krull monoids are called *positive normal affine semigroups* in [BH93]. From [BH93, 6.1.10], we obtain the following characterization of these monoids:

**2.4 Proposition.** *The following conditions on a semigroup  $\Lambda$  are equivalent:*

- (i)  $\Lambda$  is a finitely generated Krull monoid.
- (ii)  $\Lambda \cong G \cap \mathbb{N}_0^{(t)}$  for some positive integer  $t$  and some subgroup  $G$  of  $\mathbb{Z}^{(t)}$ .  
(That is,  $\Lambda$  is isomorphic to a full subsemigroup of  $\mathbb{N}_0^{(t)}$ .)
- (iii)  $\Lambda \cong W \cap \mathbb{N}_0^{(u)}$  for some positive integer  $u$  and some  $\mathbb{Q}$ -subspace  $W$  of  $\mathbb{Q}^{(n)}$ . (That is,  $\Lambda$  is isomorphic to an expanded subsemigroup of  $\mathbb{N}_0^{(u)}$ .)

(iv) There exist positive integers  $m$  and  $n$ , and an  $m \times n$  matrix  $\alpha$  over  $\mathbb{Z}$ , such that  $\Lambda \cong \mathbb{N}^{(n)} \cap \ker(\alpha)$ .

Observe that the descriptors “full” and “expanded” refer specifically to a given embedding of a semigroup into a free semigroup, while the definition of a Krull monoid is intrinsic. In addition, note that the group  $G$  and the vector space  $W$  are not mysterious; they are the group, resp. vector space, generated by  $\Lambda$ .

It’s obvious that every expanded subsemigroup of  $\mathbb{N}^{(t)}$  is also a full subsemigroup, but the converse can fail. For example, the semigroup

$$\Lambda = \left\{ \begin{bmatrix} x \\ y \end{bmatrix} \in \mathbb{N}_0^{(2)} \mid x \equiv y \pmod{3} \right\}$$

of  $\mathbb{N}_0^{(2)}$  is not the restriction to  $\mathbb{N}_0^{(2)}$  of the kernel of a matrix, so is not expanded. However,  $\Lambda$  is isomorphic to

$$\Lambda' = \left\{ \begin{bmatrix} x \\ y \\ z \end{bmatrix} \in \mathbb{N}_0^{(3)} \mid x + 2y = 3z \right\}.$$

As this example indicates, the number  $u$  of (iii) might be larger than the number  $t$  of (ii).

Condition (iv) says that a finitely generated Krull monoid can be regarded as the collection of non-negative integer solutions of a homogeneous system of linear equations. For this reason these monoids are sometimes called *Diophantine* monoids.

The key to understanding the monoids  $V(R)$  and  $+(M)$  is knowing which modules over the completion  $\widehat{R}$  actually come from  $R$ -modules. Recall that if  $R \rightarrow S$  is a ring homomorphism, we say that an  $S$ -module  $N$  is *extended* (from  $R$ ) provided there is an  $R$ -module  $M$  such that  $N \cong S \otimes_R M$ . In the

two remaining sections, we will prove criteria—one in dimension one, and one in dimension two—for identifying which finitely generated modules over the completion  $\widehat{R}$  of a local ring  $R$  are extended. In both cases, a key ingredient is that modules of finite length are *always* extended. We leave the proof of this fact as an exercise.

**2.5 Lemma.** *Let  $R$  be a local ring with completion  $\widehat{R}$ , and let  $L$  be an  $\widehat{R}$ -module of finite length. Then  $L$  also has finite length as an  $R$ -module, and the natural map  $L \rightarrow \widehat{R} \otimes_R L$  is an isomorphism.  $\square$*

## §2 Realization in dimension one

In dimension one, a beautiful result due to Levy and Odenthal [LO96] tells us exactly which  $\widehat{R}$ -modules are extended from  $R$ . See Corollary 2.8 below. First, we define for any one-dimensional local ring  $(R, \mathfrak{m}, k)$  the *Artinian localization*  $K(R)$  by  $K(R) = U^{-1}R$ , where  $U$  is the complement of the union of the minimal prime ideals (the prime ideals distinct from  $\mathfrak{m}$ ). If  $R$  is CM, then  $K(R)$  is just the total quotient ring  $\{\text{non-zerodivisors}\}^{-1}R$  as in Chapter 4. If  $R$  is not CM, then the natural map  $R \rightarrow K(R)$  is not injective.

**2.6 Proposition.** *Let  $(R, \mathfrak{m}, k)$  be a one-dimensional local ring, and let  $N$  be a finitely generated  $\widehat{R}$ -module. Then  $N$  is extended from  $R$  if and only if  $K(\widehat{R}) \otimes_{\widehat{R}} N$  is extended from  $K(R)$ .*

*Proof.* To simplify notation, we set  $K = K(R)$  and  $L = K(\widehat{R})$ . (Keep in mind, however, that these are not fields.) If  $\mathfrak{q}$  is a minimal prime ideal of  $\widehat{R}$ , then  $\mathfrak{q} \cap R$  is a minimal prime ideal of  $R$ , since “going down” holds for flat

extensions [BH93, Lemma A.9]. Therefore the inclusion  $R \rightarrow \widehat{R}$  induces a homomorphism  $K \rightarrow L$ , and this homomorphism is faithfully flat, since the map  $\text{Spec}(\widehat{R}) \rightarrow \text{Spec}(R)$  is surjective [BH93, Lemma A.10]. The “only if” direction is then clear from  $L \otimes_K K \otimes_R M \cong L \otimes_{\widehat{R}} \widehat{R} \otimes_R M$ .

For the converse, let  $X$  be a finitely generated  $K$ -module such that  $L \otimes_K X \cong L \otimes_{\widehat{R}} N$ . Since  $K$  is a localization of  $R$ , there is a finitely generated  $R$ -module  $M$  such that  $K \otimes_R M \cong X$ . Since  $L \otimes_{\widehat{R}} N \cong L \otimes_{\widehat{R}} (\widehat{R} \otimes_R M)$ , there is a homomorphism  $\varphi: N \rightarrow \widehat{R} \otimes_R M$  inducing an isomorphism from  $L \otimes_{\widehat{R}} N$  to  $L \otimes_{\widehat{R}} (\widehat{R} \otimes_R M)$ . Then the kernel  $U$  and cokernel  $V$  of  $\varphi$  have finite length and therefore are extended by Lemma 2.5. Now we break the exact sequence

$$0 \rightarrow U \rightarrow N \rightarrow S \otimes_R M \rightarrow V \rightarrow 0$$

into two short exact sequences:

$$0 \rightarrow U \rightarrow N \rightarrow W \rightarrow 0$$

$$0 \rightarrow W \rightarrow \widehat{R} \otimes_R M \rightarrow V \rightarrow 0.$$

Applying (ii) of Lemma 2.7 below to the second short exact sequence, we see that  $W$  is extended. Now we apply (i) of the lemma to the first short exact sequence, to conclude that  $N$  is extended.  $\square$

**2.7 Lemma.** *Let  $(R, \mathfrak{m})$  be a local ring with completion  $\widehat{R}$ , and let*

$$0 \rightarrow X \rightarrow Y \rightarrow Z \rightarrow 0$$

*be an exact sequence of finitely generated  $\widehat{R}$ -modules.*

- (i) *Assume  $X$  and  $Z$  are extended. If  $\text{Ext}_{\widehat{R}}^1(Z, X)$  has finite length as an  $R$ -module (e.g. if  $Z$  is locally free on the punctured spectrum of  $\widehat{R}$ ), then  $Y$  is extended.*

- (ii) Assume  $Y$  and  $Z$  are extended. If  $\text{Hom}_{\widehat{R}}(Y, Z)$  has finite length as an  $R$ -module (e.g. if  $Z$  has finite length), then  $X$  is extended.
- (iii) Assume  $X$  and  $Y$  are extended. If  $\text{Hom}_{\widehat{R}}(X, Y)$  has finite length as an  $R$ -module (e.g. if  $X$  has finite length), then  $Z$  is extended.

*Proof.* For (i), write  $X = \widehat{R} \otimes_R X_0$  and  $Z = \widehat{R} \otimes_R Z_0$ , where  $X_0$  and  $Z_0$  are finitely generated  $R$ -modules. The natural map

$$\widehat{R} \otimes_R \text{Ext}_R^1(Z_0, X_0) \longrightarrow \text{Ext}_{\widehat{R}}^1(Z, X)$$

is an isomorphism since  $Z_0$  is finitely presented, and  $\text{Ext}_R^1(Z_0, X_0)$  has finite length by faithful flatness. Therefore the natural map  $\text{Ext}_R^1(Z_0, X_0) \longrightarrow \widehat{R} \otimes_R \text{Ext}_R^1(Z_0, X_0)$  is an isomorphism by Lemma 2.5. Combining the two isomorphisms, we see that the given exact sequence, regarded as an element of  $\text{Ext}_{\widehat{R}}^1(Z, X)$ , comes from a short exact sequence  $0 \longrightarrow X_0 \longrightarrow Y_0 \longrightarrow Z_0 \longrightarrow 0$ . Clearly, then,  $\widehat{R} \otimes_R Y_0 \cong Y$ .

To prove (ii), we write  $Y = \widehat{R} \otimes_R Y_0$  and  $Z = \widehat{R} \otimes_R Z_0$ , where  $Y_0$  and  $Z_0$  are finitely generated  $R$ -modules. As in the proof of (i) we see that the natural map  $\text{Hom}_R(Y_0, Z_0) \longrightarrow \text{Hom}_{\widehat{R}}(Y, Z)$  is an isomorphism. Therefore the given  $\widehat{R}$ -homomorphism  $\beta: Y \longrightarrow Z$  comes from a homomorphism  $\beta_0: Y_0 \longrightarrow Z_0$  in  $\text{Hom}_R(Y_0, Z_0)$ . Clearly, then,  $X \cong \widehat{R} \otimes_R (\ker \beta_0)$ . The proof of (iii) is essentially the same: Write  $Y = \widehat{R} \otimes_R Y_0$  and  $X = \widehat{R} \otimes_R X_0$ ; show that  $\alpha: X \longrightarrow Y$  comes from some  $\alpha_0 \in \text{Hom}_R(X_0, Y_0)$ , and deduce that  $Z \cong \widehat{R} \otimes_R (\text{cok } \alpha_0)$ .  $\square$

**2.8 Corollary** ([LO96]). *Let  $(R, \mathfrak{m}, k)$  be a one-dimensional local ring whose completion  $\widehat{R}$  is reduced, and let  $N$  be a finitely generated  $\widehat{R}$ -module. Then  $N$  is extended from  $R$  if and only if  $\dim_{\widehat{R}_{\mathfrak{p}}} (N_{\mathfrak{p}}) = \dim_{\widehat{R}_{\mathfrak{q}}} (N_{\mathfrak{q}})$  (vector space*

*dimension) whenever  $\mathfrak{p}$  and  $\mathfrak{q}$  are minimal prime ideals of  $\widehat{R}$  lying over the same prime ideal of  $R$ . In particular, if  $R$  is a domain, then  $N$  is extended if and only if  $N$  has constant rank.*

This gives us a strategy for producing strange direct-sum behavior:

- (i) Find a one-dimensional domain  $R$  whose completion is reduced but has lots of minimal primes.
- (ii) Build indecomposable  $\widehat{R}$ -modules with highly non-constant ranks.
- (iii) Put them together in different ways to get constant-rank modules.

Suppose, to illustrate, that  $R$  is a domain whose completion  $\widehat{R}$  has two minimal primes  $\mathfrak{p}$  and  $\mathfrak{q}$ . Suppose we can build indecomposable  $\widehat{R}$ -modules  $U, V, W$  and  $X$ , with ranks  $(\dim_{\widehat{R}_{\mathfrak{p}}}(-), \dim_{\widehat{R}_{\mathfrak{q}}}(-)) = (2, 0), (0, 2), (2, 1)$ , and  $(1, 2)$ , respectively. Then  $U \oplus V$  has constant rank  $(2, 2)$ , so is extended; say,  $U \oplus V \cong \widehat{M}$ . Similarly, there are  $R$ -modules  $N, F$  and  $G$  such that  $V \oplus W \oplus W \cong \widehat{N}$ ,  $W \oplus X \cong \widehat{F}$ , and  $U \oplus X \oplus X \cong \widehat{G}$ . Using KRS over  $\widehat{R}$ , we see easily that no non-zero proper direct summand of any of the modules  $\widehat{M}, \widehat{N}, \widehat{F}, \widehat{G}$  has constant rank. It follows from Corollary 2.8 that  $M, N, F$ , and  $G$  are indecomposable, and of course no two of them are isomorphic since (again by KRS) their completions are pairwise non-isomorphic. Finally, we see that  $M \oplus F \oplus F \cong N \oplus G$ , since the two modules have isomorphic completions. Thus we easily obtain a mild violation of KRS uniqueness over  $R$ .

It's easy to accomplish (i), getting a one-dimensional domain with a lot of splitting but no ramification. In order to facilitate (ii), however, we want

to ensure that each analytic branch has infinite Cohen-Macaulay type. The following construction from [Wie01] does the job nicely:

**2.9 Construction** ([Wie01, (2.3)]). Fix a positive integer  $s$ , and let  $k$  be any field with  $|k| \geq s$ . Choose distinct elements  $t_1, \dots, t_s \in k$ . Let  $\Sigma$  be the complement of the union of the maximal ideals  $(x - t_i)k[x]$ ,  $i = 1, \dots, s$ . We define  $R$  by the pullback diagram

$$(2.9.1) \quad \begin{array}{ccc} R & \longrightarrow & \Sigma^{-1}k[x] \\ \downarrow & & \downarrow \pi \\ k & \longrightarrow & \frac{\Sigma^{-1}k[x]}{(x - t_1)^4 \cdots (x - t_s)^4}, \end{array}$$

where  $\pi$  is the natural quotient map. Then  $R$  is a one-dimensional local domain, (2.9.1) is the conductor square for  $R$  (cf. Construction 4.1), and  $\widehat{R}$  is reduced with exactly  $s$  minimal prime ideals. Indeed, we can rewrite the bottom line  $R_{\text{art}}$  as  $k \hookrightarrow D_1 \times \cdots \times D_s$ , where  $D_i \cong k[x]/(x^4)$  for each  $i$ . The conductor square for the completion is then

$$\begin{array}{ccc} \widehat{R} & \longrightarrow & T_1 \times \cdots \times T_s \\ \downarrow & & \downarrow \pi \\ k & \longrightarrow & D_1 \times \cdots \times D_s, \end{array}$$

where each  $T_i$  is isomorphic to  $k[[x]]$ . (If  $\text{char}(k) \neq 2, 3$ , then  $R$  is the ring of rational functions  $f \in k(T)$  such that  $f(t_1) = \cdots = f(t_s) \neq \infty$  and the derivatives  $f', f''$  and  $f'''$  vanish at each  $t_i$ .)

Let  $\mathfrak{p}_1, \dots, \mathfrak{p}_s$  be the minimal prime ideals of  $\widehat{R}$ . Define the *rank* of a finitely generated  $\widehat{R}$ -module  $N$  to be the  $s$ -tuple  $(r_1, \dots, r_s)$ , where  $r_i$  is the dimension of  $N_{\mathfrak{p}_i}$  as a vector space over  $R_{\mathfrak{p}_i}$ .

The next theorem says that even the case  $s = 2$  of this example yields the pathology discussed after Corollary 2.8.

**2.10 Theorem** ([Wie01, (2.4)]). *Fix a positive integer  $s$ , and let  $R$  be the ring of Construction 2.9. Let  $(r_1, \dots, r_s)$  be any sequence of non-negative integers with not all the  $r_i$  equal to zero. Then  $\widehat{R}$  has an indecomposable MCM module  $N$  with  $\text{rank}(N) = (r_1, \dots, r_s)$ .*

*Proof.* Set  $P = T_1^{(r_1)} \times \dots \times T_s^{(r_s)}$ , a projective module over  $\widehat{R} \cong T_1 \times \dots \times T_s$ . Lemma 2.11 below, a jazzed-up version of Theorem 3.5, yields an indecomposable  $\widehat{R}_{\text{art}}$ -module  $V \hookrightarrow W$  with  $W = D_1^{(r_1)} \times \dots \times D_s^{(r_s)}$ . Since  $P/cP \cong W$ , Construction 4.1 implies that there exists a torsion-free  $\widehat{R}$ -module  $M$ , namely, the pullback of  $P$  and  $V$  over  $W$ , such that  $M_{\text{art}} = (V \hookrightarrow W)$ . NAK implies that  $M$  is indecomposable, and the ranks of  $M$  at the minimal primes are precisely  $(r_1, \dots, r_s)$ .  $\square$

We leave the proof of the next lemma as a challenging exercise (Exercise 2.24).

**2.11 Lemma.** *Let  $k$  be a field. Fix an integer  $s \geq 1$ , set  $D_i = k[x]/(x^4)$  for  $i = 1, \dots, s$ , and let  $D = D_1 \times \dots \times D_s$ . Let  $(r_1, \dots, r_s)$  be an  $s$ -tuple of non-negative integers with at least one positive entry, and assume that  $r_1 \geq r_i$  for every  $i$ . Then the Artinian pair  $k \hookrightarrow D$  has an indecomposable module  $V \hookrightarrow W$ , where  $W = D_1^{(r_1)} \times \dots \times D_s^{(r_s)}$ .*

Recalling Condition (iv) of Proposition 2.4, we say that the finitely generated Krull semigroup  $\Lambda$  can be defined by  $m$  equations provided  $\Lambda \cong \mathbb{N}_0^{(n)} \cap \ker(\alpha)$  for some  $n$  and some  $m \times n$  integer matrix  $\alpha$ . Given such

an embedding of  $\Lambda$  in  $\mathbb{N}_0^{(n)}$ , we say a column vector  $\lambda \in \Lambda$  is *strictly positive* provided each of its entries is a positive integer. By decreasing  $n$  (and removing some columns from  $\alpha$ ) if necessary, we can harmlessly assume, without changing  $m$ , that  $\Lambda$  contains a strictly positive element  $\lambda$ . Specifically, choose an element  $\lambda \in \Lambda$  with the largest number of strictly positive coordinates, and throw away all the columns corresponding to zero entries of  $\lambda$ . If any element  $\lambda' \in \Lambda$  had a non-zero entry in one of the deleted columns, then  $\lambda + \lambda'$  would have more positive entries than  $\lambda$ , a contradiction.

**2.12 Theorem** ([Wie01, Theorem 2.1]). *Fix a non-negative integer  $m$ , and consider the ring  $R$  of Construction 2.9 obtained from  $s = m + 1$ . Let  $\Lambda$  be a finitely generated Krull semigroup defined by  $m$  equations and containing a strictly positive element  $\lambda$ . Then there exist a torsion-free  $R$ -module  $M$  and a commutative diagram*

$$\begin{array}{ccc} \Lambda & \xrightarrow{\quad} & \mathbb{N}_0^{(n)} \\ \varphi \downarrow & & \downarrow \psi \\ +(M) & \xrightarrow{j} & +(\widehat{R} \otimes_R M) \end{array}$$

in which

- (i)  $j$  is the natural map taking  $[N]$  to  $[\widehat{R} \otimes_R N]$ ,
- (ii)  $\varphi$  and  $\psi$  are semigroup isomorphisms, and
- (iii)  $\varphi(\lambda) = [M]$ .

*Proof.* We have  $\Lambda = \mathbb{N}_0^{(n)} \cap \ker(\alpha)$ , where  $\alpha = [a_{ij}]$  is an  $m \times n$  matrix over  $\mathbb{Z}$ . Choose a positive integer  $h$  such that  $a_{ij} + h \geq 0$  for all  $i, j$ . For  $j = 1, \dots, n$ ,

choose, using Theorem 2.10, a MCM  $\widehat{R}$ -module  $L_j$  such that  $\text{rank}(L_j) = (a_{1j} + h, \dots, a_{mj} + h, h)$ .

Given any column vector  $\beta = [b_1, b_2, \dots, b_n]^{\text{tr}} \in \mathbb{N}_0^{(n)}$ , put  $N_\beta = L_1^{(b_1)} \oplus \dots \oplus L_n^{(b_n)}$ . The rank of  $N_\beta$  is

$$\left( \sum_{j=1}^n (a_{1j} + h) b_j, \dots, \sum_{j=1}^n (a_{mj} + h) b_j, \left( \sum_{j=1}^n b_j \right) h \right).$$

Since  $R$  is a domain, Corollary 2.8 implies that  $N_\beta$  is in the image of  $j: \mathbf{V}(R) \rightarrow \mathbf{V}(\widehat{R})$  if and only if  $\sum_{j=1}^n (a_{ij} + h) b_j = \left( \sum_{j=1}^n b_j \right) h$  for each  $i$ , that is, if and only if  $\beta \in \mathbb{N}_0^{(n)} \cap \ker(\alpha) = \Lambda$ . To complete the proof, we let  $M$  be the  $R$ -module (unique up to isomorphism) such that  $\widehat{M} \cong N_\lambda$ .  $\square$

This corollary makes it very easy to demonstrate spectacular failure of KRS uniqueness:

**2.13 Example.** Let

$$\Lambda = \left\{ \begin{bmatrix} x \\ y \\ z \end{bmatrix} \in \mathbb{N}_0^{(3)} \mid 72x + y = 73z \right\}.$$

This has three atoms (minimal non-zero elements), namely

$$\alpha = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}, \quad \beta = \begin{bmatrix} 0 \\ 73 \\ 1 \end{bmatrix}, \quad \gamma = \begin{bmatrix} 73 \\ 0 \\ 72 \end{bmatrix}.$$

Note that  $73\alpha = \beta + \gamma$ . Taking  $s = 2$  in Construction 2.9, we get a local ring  $R$  and indecomposable  $R$ -modules  $A, B, C$  such that  $A^{(t)}$  has only the obvious direct-sum decompositions for  $t \leq 72$ , but  $A^{(73)} \cong B \oplus C$ .

We define the *splitting number*  $\text{spl}(R)$  of a one-dimensional local ring  $R$  by

$$\text{spl}(R) = |\text{Spec}(\widehat{R})| - |\text{Spec}(R)|.$$

The splitting number of the ring  $R$  in Construction 2.9 is  $s - 1$ . Corollary 2.12 says that every finitely generated Krull monoid defined by  $m$  equations can be realized as  $+(M)$  for some finitely generated module over a one-dimensional local ring (in fact, a domain essentially of finite type over  $\mathbb{Q}$ ) with splitting number  $m$ . This is the best possible:

**2.14 Proposition.** *Let  $M$  be a finitely generated module over a one-dimensional local ring  $R$  with splitting number  $m$ . The embedding  $+(M) \hookrightarrow V(\widehat{R})$  exhibits  $+(M)$  as an expanded subsemigroup of the free semigroup  $+(\widehat{R} \otimes_R M)$ . Moreover,  $+(M)$  is defined by  $m$  equations.*

*Proof.* Write  $\widehat{R} \otimes_R M = V_1^{(e_1)} \oplus \cdots \oplus V_n^{(e_n)}$ , where the  $V_j$  are pairwise non-isomorphic indecomposable  $\widehat{R}$ -modules and the  $e_i$  are all positive. We have an embedding  $+(M) \hookrightarrow \mathbb{N}_0^{(n)}$  taking  $[N]$  to  $[b_1, \dots, b_n]^{\text{tr}}$ , where  $\widehat{R} \otimes_R N \cong V_1^{(b_1)} \oplus \cdots \oplus V_n^{(b_n)}$ , and we identify  $+(M)$  with its image  $\Lambda$  in  $\mathbb{N}_0^{(n)}$ . Given a prime  $\mathfrak{p} \in \text{Spec}(R)$  with, say,  $t$  primes  $\mathfrak{q}_1, \dots, \mathfrak{q}_t$  lying over it, there are  $t - 1$  homogeneous linear equations on the  $b_j$  that say that  $\widehat{N}$  has constant rank on the fiber over  $\mathfrak{p}$  (cf. Corollary 2.8). Letting  $\mathfrak{p}$  vary over  $\text{Spec}(R)$ , we obtain exactly  $m = \text{spl}(R)$  equations that must be satisfied by elements of  $\Lambda$ . Conversely, if the  $b_j$  satisfy these equations, then  $N := V_1^{(b_1)} \oplus \cdots \oplus V_n^{(b_n)}$  has constant rank on each fiber of  $\text{Spec}(\widehat{R}) \rightarrow \text{Spec}(R)$ . By Corollary 2.8,  $N$  is extended from an  $R$ -module, say  $N \cong \widehat{R} \otimes_R L$ . Clearly  $\widehat{R} \otimes_R L \mid \widehat{M}^{(u)}$  if  $u$  is large enough, and it follows from Proposition 2.19 that  $L \in +(M)$ , whence  $[b_1, \dots, b_n]^{\text{tr}} \in \Lambda$ .  $\square$

In [Kat02] K. Kattchee showed that, for each  $m$ , there is a finitely generated Krull monoid  $\Lambda$  that cannot be defined by  $m$  equations. Thus no

single one-dimensional local ring can realize *every* finitely generated Krull monoid in the form  $+(M)$  for a finitely generated module  $M$ .

### §3 Realization in dimension two

Suppose we have a finitely generated Krull semigroup  $\Lambda$  and a full embedding  $\Lambda \subseteq \mathbb{N}_0^{(t)}$ , i.e.  $\Lambda$  is the intersection of  $\mathbb{N}^{(t)}$  with a subgroup of  $\mathbb{Z}^{(t)}$ . By Proposition 2.14, we cannot realize this embedding in the form  $+(M) \hookrightarrow +(\widehat{R} \otimes_R M)$  for a module  $M$  over a one-dimensional local ring  $R$  unless  $\Lambda$  is actually an *expanded* subsemigroup of  $\mathbb{N}_0^{(t)}$ , i.e. the intersection of  $\mathbb{N}^{(t)}$  with a subspace of  $\mathbb{Q}^{(t)}$ . If, however, we go to a two-dimensional ring, then we can realize  $\Lambda$  as  $+(M)$ , though the ring that does the realizing is less tractable than the one-dimensional rings that realize expanded subsemigroups.

As in the last section, we need a criterion for an  $\widehat{R}$ -module to be extended from  $R$ . For general two-dimensional rings, we know of no such criterion, so we shall restrict to analytically normal domains. (A local domain  $(R, \mathfrak{m})$  is *analytically normal* provided its completion  $(\widehat{R}, \widehat{\mathfrak{m}})$  is also a normal domain.)

We recall two facts from Bourbaki [Bou98, Chapter VII]. Firstly, over a Noetherian normal domain  $R$  one can assign to each finitely generated  $R$ -module  $M$  a *divisor class*  $\text{cl}(M) \in \text{Cl}(R)$  in such a way that

- (i) Taking divisor classes  $\text{cl}(-)$  is additive on exact sequences, and
- (ii) if  $J$  is a fractional ideal of  $R$ , then  $\text{cl}(J)$  is the isomorphism class  $[J^{**}]$  of the divisorial (i.e. reflexive) ideal  $J^{**}$ , where  $-^*$  denotes the dual  $\text{Hom}_R(-, R)$ .

Secondly, each finitely generated torsion-free module  $M$  over a Noetherian normal domain  $R$  has a “Bourbaki sequence,” namely a short exact sequence

$$(2.14.1) \quad 0 \longrightarrow F \longrightarrow M \longrightarrow J \longrightarrow 0$$

wherein  $F$  is a free  $R$ -module and  $J$  is an ideal of  $R$ .

The following criterion for a module to be extended is Proposition 3 of [RWW99] (cf. also [Wes88, (1.5)]).

**2.15 Proposition.** *Let  $R$  be a two-dimensional local ring whose  $\mathfrak{m}$ -adic completion  $\widehat{R}$  is a normal domain. Let  $N$  be a finitely generated torsion-free  $\widehat{R}$ -module. Then  $N$  is extended from  $R$  if and only if  $\text{cl}(N)$  is in the image of the natural homomorphism  $\Phi: \text{Cl}(R) \longrightarrow \text{Cl}(\widehat{R})$ .*

*Proof.* Suppose  $N \cong \widehat{R} \otimes_R M$ . Then  $M$  is finitely generated and torsion-free, by faithfully flat descent. Choose a Bourbaki sequence (2.14.1) for  $M$ ; tensoring with  $\widehat{R}$  and using the additivity of  $\text{cl}(-)$  on short exact sequences, we find

$$\text{cl}(N) = \text{cl}(\widehat{R} \otimes_R J) = [(\widehat{R} \otimes_R J)^{**}] = \Phi(\text{cl}(J)).$$

For the converse, choose a Bourbaki sequence

$$0 \longrightarrow G \longrightarrow N \longrightarrow L \longrightarrow 0$$

over  $\widehat{R}$ , so that  $G$  is a free  $\widehat{R}$ -module and  $L$  is an ideal of  $\widehat{R}$ . Then  $\text{cl}(L) = \text{cl}(N)$ , and since  $\text{cl}(N)$  is in the image of  $\Phi$  there is a divisorial ideal  $I$  of  $R$  such that  $\widehat{R} \otimes_R I \cong L^{**}$ . Set  $V = L^{**}/L$ . Then  $V$  has finite length and hence is extended by Lemma 2.5; it follows from Lemma 2.7(i) and the short exact

sequence  $0 \rightarrow L \rightarrow L^{**} \rightarrow V \rightarrow 0$  that  $L$  is extended. Moreover,  $\widehat{R}_{\mathfrak{p}}$  is a discrete valuation ring for each height-one prime ideal  $\mathfrak{p}$ , so that  $\text{Ext}_{\widehat{R}}^1(I, G)$  has finite length. Now Lemma 2.7(ii) says that  $N$  is extended since  $G$  and  $L$  are.  $\square$

As in the last section, we need to guarantee that the complete ring  $\widehat{R}$  has a sufficiently rich supply of MCM modules.

**2.16 Lemma** ([Wie01, Lemma 3.2]). *Let  $s$  be any positive integer. There is a complete local normal domain  $B$ , containing  $\mathbb{C}$ , such that  $\dim(B) = 2$  and  $\text{Cl}(B)$  contains a copy of  $(\mathbb{R}/\mathbb{Z})^{(s)}$ .*

*Proof.* Choose a positive integer  $d$  such that  $(d-1)(d-2) \geq s$ , and let  $V$  be a smooth projective plane curve of degree  $d$  over  $\mathbb{C}$ . Let  $A$  be the homogeneous coordinate ring of  $V$  for some embedding  $V \hookrightarrow \mathbb{P}_{\mathbb{C}}^2$ . Then  $A$  is a two-dimensional normal domain, by [Har77, Chap. II, Exercise 8.4(b)]. By [Har77, Appendix B, Sect. 5],  $\text{Pic}^0(V) \cong D := (\mathbb{R}/\mathbb{Z})^{2g}$ , where  $g = \frac{1}{2}(d-1)(d-2)$ , the genus of  $V$ . Here  $\text{Pic}^0(V)$  is the kernel of the degree map  $\text{Pic}(V) \rightarrow \mathbb{Z}$ , so  $\text{Cl}(V) = \text{Pic}(V) = D \oplus \mathbb{Z}\sigma$ , where  $\sigma$  is the class of a divisor of degree 1. There is a short exact sequence

$$0 \rightarrow \mathbb{Z} \rightarrow \text{Cl}(V) \rightarrow \text{Cl}(A) \rightarrow 0,$$

in which  $1 \in \mathbb{Z}$  maps to the divisor class  $\tau := [H \cdot V]$ , where  $H$  is a line in  $\mathbb{P}_{\mathbb{C}}^2$ . (Cf. [Har77, Chap. II, Exercise 6.3].) Thus  $\text{Cl}(A) \cong \text{Cl}(V)/\mathbb{Z}\tau$ . Since  $\tau$  has degree  $d$ , we see that  $\tau - d\sigma \in D$ . Choose an element  $\delta \in D$  with  $d\delta = \tau - d\sigma$ . Recalling that  $\text{Cl}(V) = \text{Pic}(V) = D \oplus \mathbb{Z}\sigma$ , we define a surjection  $f: \text{Cl}(V) \rightarrow D \oplus \mathbb{Z}/(d)$  by sending  $x \in D$  to  $(x, 0)$  and  $\sigma$  to  $(-\delta, 1 + (d))$ . Then  $\ker(f) = \mathbb{Z}\tau$ , so  $\text{Cl}(A) \cong D \oplus \mathbb{Z}/d\mathbb{Z}$ .

Let  $\mathfrak{P}$  be the irrelevant maximal ideal of  $A$ . By [Har77, Chap. II, Exercise 6.3(d)],  $\text{Cl}(A_{\mathfrak{P}}) \cong \text{Cl}(A)$ . The  $\mathfrak{P}$ -adic completion  $B$  of  $A$  is an integrally closed domain, by [ZS75, Chap. VIII, Sect. 13]. Moreover  $\text{Cl}(A_{\mathfrak{P}}) \rightarrow \text{Cl}(B)$  is injective by faithfully flat descent, so  $\text{Cl}(B)$  contains a copy of  $D = (\mathbb{R}/\mathbb{Z})^{(d-1)(d-2)}$ , which, in turn, contains a copy of  $(\mathbb{R}/\mathbb{Z})^{(s)}$ .  $\square$

We now have everything we need to prove our realization theorem for full subsemigroups of  $\mathbb{N}_0^{(t)}$ .

**2.17 Theorem.** *Let  $t$  be a positive integer, and let  $\Lambda$  be a full subsemigroup of  $\mathbb{N}_0^{(t)}$ . Assume that  $\Lambda$  contains an element  $\lambda$  with strictly positive entries. Then there exist a two-dimensional local unique factorization domain  $R$ , a finitely generated reflexive (= MCM)  $R$ -module  $M$ , and a commutative diagram of semigroups*

$$\begin{array}{ccc} \Lambda & \xrightarrow{\quad} & \mathbb{N}_0^{(t)} \\ \varphi \downarrow & & \downarrow \psi \\ +(M) & \xrightarrow{j} & +(\widehat{R} \otimes_R M) \end{array}$$

in which

- (i)  $j$  is the natural map taking  $[N]$  to  $[\widehat{R} \otimes_R N]$ ,
- (ii)  $\varphi$  and  $\psi$  are isomorphisms, and
- (iii)  $\varphi(\lambda) = [M]$ .

*Proof.* Let  $G$  be the subgroup of  $\mathbb{Z}^{(t)}$  generated by  $\Lambda$ , and write  $\mathbb{Z}^{(t)}/G = C_1 \oplus \cdots \oplus C_s$ , where each  $C_i$  is a cyclic group. Then  $\mathbb{Z}^{(t)}/G$  can be embedded in  $(\mathbb{R}/\mathbb{Z})^{(s)}$ .

Let  $B$  be the complete local domain provided by Lemma 2.16. Since  $\mathbb{Z}^{(t)}/G$  embeds in  $\text{Cl}(B)$ , there is a group homomorphism  $\varpi: \mathbb{Z}^{(t)} \rightarrow \text{Cl}(B)$  with  $\ker(\varpi) = G$ . Let  $\{e_1, \dots, e_t\}$  be the standard basis of  $\mathbb{Z}^{(t)}$ . For each  $i \leq t$ , write  $\varpi(e_i) = [L_i]$ , where  $L_i$  is a divisorial ideal of  $B$  representing the divisor class of  $\varpi(e_i)$ .

Next we use Heitmann's amazing theorem [Hei93], which implies that  $B$  is the completion of some local unique factorization domain  $R$ . For each element  $m = (m_1, \dots, m_t) \in \mathbb{N}_0^{(t)}$ , we let  $\psi(m)$  be the isomorphism class of the  $B$ -module  $L_1^{(m_1)} \oplus \dots \oplus L_t^{(m_t)}$ . The divisor class of this module is  $m_1[L_1] + \dots + m_t[L_t] = \varpi(m_1, \dots, m_t)$ . By Proposition 2.15, the module  $L_1^{(m_1)} \oplus \dots \oplus L_t^{(m_t)}$  is the completion of an  $R$ -module if and only if its divisor class is trivial, that is, if and only if  $m \in G \cap \mathbb{N}_0^{(t)}$ . But  $m \in G \cap \mathbb{N}_0^{(t)} = \Lambda$ , since  $\Lambda$  is a full subsemigroup of  $\mathbb{N}_0^{(t)}$ . Therefore  $L_1^{(m_1)} \oplus \dots \oplus L_t^{(m_t)}$  is the completion of an  $R$ -module if and only if  $m \in \Lambda$ . If  $m \in \Lambda$ , we let  $\varphi(m)$  be the isomorphism class of a module whose completion is isomorphic to  $L_1^{(m_1)} \oplus \dots \oplus L_t^{(m_t)}$ . In particular, choosing a module  $M$  such that  $[M] = \varphi(\lambda)$ , we get the desired commutative diagram.  $\square$

## §4 Flat local homomorphisms

Here we prove a generalization (Proposition 2.19) of the fact that  $V(R) \rightarrow V(\widehat{R})$  is a divisor homomorphism. We begin with a general result that does not even require the ring to be local.

**2.18 Proposition** ([Wie98, Theorem 1.1]). *Let  $A \rightarrow B$  be a faithfully flat homomorphism of commutative rings, and let  $U$  and  $V$  be finitely presented*

*A*-modules. Then  $U \in \text{add}_A V$  if and only if  $B \otimes_A U \in \text{add}_B(B \otimes_A V)$ .

*Proof.* The “only if” direction is clear. For the converse, we may assume, by replacing  $V$  by a direct sum of copies of  $V$ , that  $B \otimes_A U \mid B \otimes_A V$ . Choose  $B$ -homomorphisms  $B \otimes_A U \xrightarrow{\alpha} B \otimes_A V$  and  $B \otimes_A V \xrightarrow{\beta} B \otimes_A U$  such that  $\beta\alpha = 1_{B \otimes_A U}$ . Since  $V$  is finitely presented and  $B$  is flat over  $A$ , the natural map  $B \otimes_A \text{Hom}_A(V, U) \rightarrow \text{Hom}_B(B \otimes_A V, B \otimes_A U)$  is an isomorphism. Therefore we can write  $\beta = b_1 \otimes \sigma_1 + \cdots + b_r \otimes \sigma_r$ , with  $b_i \in B$  and  $\sigma_i \in \text{Hom}_A(V, U)$  for each  $i$ . Put  $\sigma = [\sigma_1 \cdots \sigma_r]: V^{(r)} \rightarrow U$ . We will show that  $\sigma$  is a split surjection. Since

$$(1_B \otimes \sigma) \begin{bmatrix} b_1 \\ \vdots \\ b_r \end{bmatrix} \alpha = 1_{B \otimes_A U},$$

we see that  $1_B \otimes \sigma: B \otimes_A V^{(r)} \rightarrow B \otimes_A U$  is a split surjection. Therefore the induced map  $(1_B \otimes \sigma)_*: \text{Hom}_B(B \otimes_A U, B \otimes_A V^{(r)}) \rightarrow \text{Hom}_B(B \otimes_A U, B \otimes_A U)$  is surjective. Since  $U$  too is finitely presented, the vertical maps in the following commutative square are isomorphisms.

$$(2.18.1) \quad \begin{array}{ccc} B \otimes_A \text{Hom}_A(U, V^{(r)}) & \xrightarrow{1_B \otimes \sigma_*} & B \otimes_A \text{Hom}_A(U, U) \\ \cong \downarrow & & \downarrow \cong \\ \text{Hom}_B(B \otimes_A U, B \otimes_A V^{(r)}) & \xrightarrow{(1_B \otimes \sigma)_*} & \text{Hom}_B(B \otimes_A U, B \otimes_A U) \end{array}$$

Therefore  $1_B \otimes \sigma_*$  is surjective as well. By faithful flatness,  $\sigma_*$  is surjective, and hence  $\sigma$  is a split surjection.  $\square$

**2.19 Proposition** ([HW09, Theorem 1.3]). *Let  $R \rightarrow S$  be a flat local homomorphism of Noetherian local rings. Then the map  $j: \mathbf{V}(R) \rightarrow \mathbf{V}(S)$  taking  $[M]$  to  $[S \otimes_R M]$  is a divisor homomorphism.*

*Proof.* Suppose  $M$  and  $N$  are finitely generated  $R$ -modules and that  $S \otimes_R M \mid S \otimes_R N$ . We want to show that  $M \mid N$ . By Theorem 1.13 it will be enough to show that  $M/\mathfrak{m}^t M \mid N/\mathfrak{m}^t N$  for all  $t \geq 1$ . By passing to the flat local homomorphism  $R/\mathfrak{m}^t \rightarrow S/\mathfrak{m}^t S$ , we may assume that  $R$  is Artinian and hence, by Corollary 1.6, that finitely generated modules satisfy KRS.

By Proposition 2.18, we know at least that  $M \mid N^{(r)}$  for some  $r \geq 1$ . By Corollary 1.9 (or Theorem 1.3 and Corollary 1.5)  $M$  is uniquely a direct sum of indecomposable modules. If  $M$  itself is indecomposable, KRS immediately implies that  $M \mid N$ . An easy induction argument using direct-sum cancellation (Corollary 1.16) completes the proof (cf. Exercise 2.20).  $\square$

## §5 Exercises

**2.20 Exercise.** Complete the proof of Proposition 2.19.

**2.21 Exercise.** A subset  $C$  of a poset  $X$  is called a *clutter* (or *antichain*) provided no two elements of  $C$  are comparable. Consider the following property of a poset  $X$ : ( $\dagger$ )  $X$  has the descending chain condition, and every clutter in  $X$  is finite. Prove that if  $X$  and  $Y$  both satisfy ( $\dagger$ ), then  $X \times Y$  (with the product partial ordering:  $(x_1, y_1) \leq (x_2, y_2) \iff x_1 \leq x_2$  and  $y_1 \leq y_2$ ) satisfies ( $\dagger$ ). Deduce Dickson's Lemma [Dic13]: Every clutter in  $\mathbb{N}_0^{(t)}$  is finite.

**2.22 Exercise.** Prove the equivalence of conditions (i)–(iv) of Proposition 2.4.

**2.23 Exercise.** Prove Lemma 2.5.

**2.24 Exercise** ([Wie01, Lemma 2.2]). Prove the existence of the indecomposable  $\widehat{R}_{\text{art}}$ -module  $V \hookrightarrow W$  in Lemma 2.11, as follows. Let  $C = k^{(r_1)}$ , viewed as column vectors. Define the “truncated diagonal”  $\partial: C \rightarrow W = D_1^{(r_1)} \times \cdots \times D_s^{(r_s)}$  by setting the  $i^{\text{th}}$  component of  $\partial([c_1, \dots, c_{r_1}]^{\text{tr}})$  equal to  $[c_1, \dots, c_{r_i}]^{\text{tr}}$ . (Here we use  $r_1 \geq r_i$  for all  $i$ .) Let  $V$  be the  $k$ -subspace of  $W$  consisting of all elements

$$\{\partial(u) + X\partial(v) + X^3\partial(Hv)\},$$

as  $u$  and  $v$  run over  $C$ , where  $X = (x, 0, \dots, 0)$  and  $H$  is the nilpotent Jordan block with 1 on the superdiagonal and 0 elsewhere.

- (i) Prove that  $W$  is generated as a  $D$ -module by all elements of the form  $\partial(u)$ ,  $u \in C$ , so that in particular  $DV = W$ . (Hint: it suffices to consider elements  $w = (w_1, \dots, w_s)$  with only one non-zero entry  $w_i$ , and such that  $w_i \in D_i^{(r_i)}$  has only one non-zero entry, which is equal to 1.)
- (ii) Prove that  $V \hookrightarrow W$  is indecomposable along the same lines as the arguments in Chapter 4. (Hint: use the fact that  $\{1, x, x^2, x^3\}$  is linearly independent over  $k$ . For additional inspiration, take a peek at the descending induction argument in Case 3.14 of the construction in the next chapter, with  $\alpha = x$ ,  $\beta = x^3$ , and  $t = 0$ .)

## *Dimension zero*

In this chapter we prove that the zero-dimensional commutative, Noetherian rings of finite representation type are exactly the Artinian principal ideal rings. We also introduce Artinian pairs, which will be used in the next chapter to classify the one-dimensional rings of finite Cohen-Macaulay type. The Drozd-Rořter conditions (DR1) and (DR2) are shown to be necessary for finite representation type in Theorem 3.5, and in Theorem 3.21 we reduce the proof of their sufficiency to some special cases, where we can appeal to the matrix calculations of Green and Reiner.

### **§1 Artinian rings with finite**

#### **Cohen-Macaulay type**

A commutative Artinian ring  $R$  with finite Cohen-Macaulay type has only finitely many indecomposable finitely generated  $R$ -modules. To see that this condition forces  $R$  to be a principal ideal ring, and in several other constructions of indecomposable modules, we use the following result:

**3.1 Lemma.** *Let  $R$  be any commutative ring,  $n$  a positive integer and  $H$  the nilpotent  $n \times n$  Jordan block with 1's on the superdiagonal and 0's elsewhere. If  $\alpha$  is an  $n \times n$  matrix over  $R$  and  $\alpha H = H\alpha$ , then  $\alpha \in R[H]$ .*

*Proof.* Let  $\alpha = [a_{ij}]$ . Left multiplication by  $H$  moves each row up one step and kills the bottom row, while right multiplication shifts each column to the right and kills the first column. The relation  $\alpha H = H\alpha$  therefore yields

the equations  $a_{i,j-1} = a_{i+1,j}$  for  $i, j = 1, \dots, n$ , with the convention that  $a_{k\ell} = 0$  if  $k = n + 1$  or  $\ell = 0$ . These equations show (a) that each of the diagonals (of slope -1) is constant and (b) that  $a_{21} = \dots = a_{n1} = 0$ . Combining (a) and (b), we see that  $\alpha$  is upper triangular. Letting  $b_j$  be the constant on the diagonal  $[a_{1,j+1} \ a_{2,j+2} \ \dots \ a_{n-j,n}]$ , for  $0 \leq j \leq n - 1$ , we see that  $\alpha = \sum_{j=0}^{n-1} b_j H^j$ .  $\square$

When  $R$  is a field (the only case we will need), there is a fancy proof:  $H$  is “cyclic” or “non-derogatory”, that is, its characteristic and minimal polynomials coincide. The centralizer of a non-derogatory matrix  $B$  is always just  $R[B]$  (cf. [Jac75, Corollary, p. 107]).

**3.2 Theorem.** *Let  $R$  be a Noetherian ring. These are equivalent:*

- (i)  *$R$  is an Artinian principal ideal ring.*
- (ii)  *$R$  has only finitely many indecomposable finitely generated modules, up to isomorphism.*
- (iii)  *$R$  is Artinian, and there is a bound on the number of generators required for indecomposable finitely generated  $R$ -modules.*

*Under these conditions, the number of isomorphism classes of indecomposable finitely generated modules is exactly the length of  $R$ .*

*Proof.* Assuming (i), we will prove (ii) and verify the last statement. Since  $R$  is a product of finitely many local rings, we may assume that  $R$  is local, with maximal ideal  $\mathfrak{m}$ . The length  $\ell$  of  $R$  is the least integer  $t$  such that  $\mathfrak{m}^t = 0$ . Since every finitely generated  $R$ -module is a direct sum of cyclic

modules, the indecomposable modules are exactly the modules  $R/\mathfrak{m}^t$ ,  $1 \leq t \leq \ell$ .

To see that (ii)  $\implies$  (iii), suppose  $R$  is not Artinian. Choose a maximal ideal  $\mathfrak{m}$  of positive height. The ideals  $\mathfrak{m}^t$ ,  $t \geq 1$  then form a strictly descending chain of ideals (cf. Exercise 3.22). Therefore the  $R$ -modules  $R/\mathfrak{m}^t$  are indecomposable and, since they have different annihilators, pairwise non-isomorphic, contradicting (ii).

To complete the proof, we show that (iii)  $\implies$  (i). Again, we may assume that  $R$  is local with maximal ideal  $\mathfrak{m}$ . Supposing  $R$  is not a principal ideal ring, we will build, for every  $n$ , an indecomposable finitely generated  $R$ -module requiring exactly  $n$  generators. By passing to  $R/\mathfrak{m}^2$ , we may assume that  $\mathfrak{m}^2 = 0$ , so that now  $\mathfrak{m}$  is a vector space over  $k := R/\mathfrak{m}$ . Choose two  $k$ -linearly independent elements  $x, y \in \mathfrak{m}$ .

Fix  $n \geq 1$ , let  $I$  be the  $n \times n$  identity matrix, and let  $H$  be the  $n \times n$  nilpotent Jordan block of Lemma 3.1. Put  $\Psi = yI + xH$  and  $M = \text{cok}(\Psi)$ . Since the entries of  $\Psi$  are in  $\mathfrak{m}$ , the  $R$ -module  $M$  needs exactly  $n$  generators.

To show that  $M$  is indecomposable, let  $f = f^2 \in \text{End}_R(M)$ , and assume that  $f \neq 1_M$ . We will show that  $f = 0$ . There exist  $n \times n$  matrices  $F$  and  $G$  over  $R$  making the following diagram commute.

$$\begin{array}{ccccccc} R^{(n)} & \xrightarrow{\Psi} & R^{(n)} & \longrightarrow & M & \longrightarrow & 0 \\ G \downarrow & & F \downarrow & & f \downarrow & & \\ R^{(n)} & \xrightarrow{\Psi} & R^{(n)} & \longrightarrow & M & \longrightarrow & 0 \end{array}$$

The equation  $F\Psi = \Psi G$  yields  $yF + xFH = yG + xHG$ . Since  $x$  and  $y$  are linearly independent, we obtain, after reducing all entries of  $F$ ,  $G$  and  $H$

modulo  $\mathfrak{m}$ , that  $\overline{F} = \overline{G}$  and  $\overline{F} \overline{H} = \overline{H} \overline{G}$ . Therefore  $\overline{F}$  and  $\overline{H}$  commute, and by Lemma 3.1  $\overline{F}$  is an upper-triangular matrix with constant diagonal.

Now  $f$  is not surjective, by Exercise 1.27, and therefore neither is  $F$ . By NAK,  $\overline{F}$  is not surjective, so  $\overline{F}$  must be strictly upper triangular. But then  $\overline{F}^n = 0$ , and it follows that  $\text{im}(f) = \text{im}(f^n) \subseteq \mathfrak{m}M$ . Now NAK implies that  $1-f$  is surjective. Since  $1-f$  is idempotent, Exercise 1.27 implies that  $f = 0$ .  $\square$

This construction is far from new. See, for example, the papers of Higman [Hig54], Heller and Reiner [HR61], and Warfield [War70]. Similar constructions can be found in the classification, up to simultaneous equivalence, of pairs of matrices. (Cf. Dieudonné's discussion [Die46] of the work of Kronecker [Kro74] and Weierstrass [Wei68].)

## §2 Artinian pairs

Here we introduce the main computational tool for building indecomposable maximal Cohen-Macaulay modules over one-dimensional rings.

**3.3 Definition.** An *Artinian pair* is a module-finite extension  $(A \hookrightarrow B)$  of commutative Artinian rings. Given an Artinian pair  $\mathbf{A} = (A \hookrightarrow B)$ , an  $\mathbf{A}$ -module is a pair  $(V \hookrightarrow W)$ , where  $W$  is a finitely generated projective  $B$ -module and  $V$  is an  $A$ -submodule of  $W$  with the property that  $BV = W$ . A morphism  $(V_1 \hookrightarrow W_1) \rightarrow (V_2 \hookrightarrow W_2)$  of  $\mathbf{A}$ -modules is a  $B$ -homomorphism from  $W_1$  to  $W_2$  that carries  $V_1$  into  $V_2$ . We say that the  $\mathbf{A}$ -module  $(V \hookrightarrow W)$  has *constant rank*  $n$  provided  $W \cong B^{(n)}$ .

With direct sums defined in the obvious way, we get an additive category  $\mathbf{A}\text{-mod}$ . To see that Theorem 1.3 applies in this context, we note first that the endomorphism ring of every  $\mathbf{A}$ -module is a module-finite  $A$ -algebra and therefore is left Artinian. Next, suppose  $\epsilon$  is an idempotent endomorphism of an  $\mathbf{A}$ -module  $\mathfrak{X} = (V \hookrightarrow W)$ . Then  $\mathfrak{Y} = (\epsilon(V) \hookrightarrow \epsilon(W))$  is also an  $\mathbf{A}$ -module. The projection  $p: \mathfrak{X} \rightarrow \mathfrak{Y}$  and inclusion  $u: \mathfrak{Y} \hookrightarrow \mathfrak{X}$  give a factorization  $\epsilon = up$ , with  $pu = 1_{\mathfrak{Y}}$ . Thus idempotents split in  $\mathbf{A}\text{-mod}$ . Combining Theorem 1.3 and Corollary 1.5, we obtain the following:

**3.4 Theorem.** *Let  $\mathbf{A}$  be an Artinian pair, and let  $\mathbf{M}_1, \dots, \mathbf{M}_s$  and  $\mathbf{N}_1, \dots, \mathbf{N}_t$  be indecomposable  $\mathbf{A}$ -modules such that  $\mathbf{M}_1 \oplus \dots \oplus \mathbf{M}_s \cong \mathbf{N}_1 \oplus \dots \oplus \mathbf{N}_t$ . Then  $s = t$ , and, after renumbering,  $\mathbf{M}_i \cong \mathbf{N}_i$  for each  $i$ .*

We say  $\mathbf{A}$  has *finite representation type* provided there are, up to isomorphism, only finitely many indecomposable  $\mathbf{A}$ -modules.

Our main result in this chapter is Theorem 3.5, which gives necessary conditions for an Artinian pair to have finite representation type. As we will see in the next chapter, these conditions are actually sufficient for finite representation type. The conditions were introduced by Drozd and Roïter [DR67] in 1966, and we will refer to them as the Drozd-Roïter conditions. (See the historical remarks in Section §2 of Chapter 4.)

**3.5 Theorem.** *Let  $\mathbf{A} = (A \hookrightarrow B)$  be an Artinian pair in which  $A$  is local, with maximal ideal  $\mathfrak{m}$  and residue field  $k$ . Assume that at least one of the following conditions fails:*

$$(dr1) \dim_k(B/\mathfrak{m}B) \leq 3$$

$$(dr2) \dim_k \left( \frac{\mathfrak{m}B + A}{\mathfrak{m}^2B + A} \right) \leq 1.$$

Let  $n$  be an arbitrary positive integer. Then there is an indecomposable  $\mathbf{A}$ -module of constant rank  $n$ . Moreover, if  $|k|$  is infinite, there are at least  $|k|$  pairwise non-isomorphic indecomposable  $\mathbf{A}$ -modules of rank  $n$ .

**3.6 Remark.** If  $k$  is infinite then the number of isomorphism classes of  $\mathbf{A}$ -modules is at most  $|k|$ . To see this, note that there are, up to isomorphism, only countably many finitely generated projective  $B$ -modules  $W$ . Also, since any such  $W$  has finite length as an  $A$ -module, we see that  $|W| \leq |k|$  and hence that  $W$  has at most  $|k|$   $A$ -submodules  $V$ . It follows that the number of possibilities for  $(V \hookrightarrow W)$  is bounded by  $\aleph_0 |k| = |k|$ .

The proof of Theorem 3.5 involves a basic construction and a dreary analysis of the many cases that must be considered in order to implement the construction.

**3.7 Assumptions.** Throughout the rest of this chapter,  $\mathbf{A} = (A \hookrightarrow B)$  is an Artinian pair in which  $A$  is local, with maximal ideal  $\mathfrak{m}$  and residue field  $k$ .

The next three results will allow us to pass to a more manageable Artinian pair  $k \hookrightarrow D$ , where  $D$  is a suitable finite-dimensional  $k$ -algebra. The proofs of the first two lemmas are exercises.

**3.8 Lemma.** Let  $C$  be a subring of  $B$  containing  $A$ . The functor  $(V \hookrightarrow W) \rightsquigarrow (V \hookrightarrow B \otimes_C W)$  from  $(A \hookrightarrow C)$ -mod to  $(A \hookrightarrow B)$ -mod is faithful and full. The functor is injective on isomorphism classes and preserves indecomposability.

□

**3.9 Lemma.** *Let  $I$  be a nilpotent ideal of  $B$ , and put  $\mathbf{E} = \left(\frac{A+I}{I} \hookrightarrow \frac{B}{I}\right)$ . The functor  $(V \hookrightarrow W) \rightsquigarrow \left(\frac{V+IW}{IW} \hookrightarrow \frac{W}{IW}\right)$ , from  $\mathbf{A}$ -mod to  $\mathbf{E}$ -mod, is surjective on isomorphism classes and reflects indecomposable objects.  $\square$*

**3.10 Proposition.** *Let  $A \hookrightarrow B$  be an Artinian pair for which either (dr1) or (dr2) fails. There is a ring  $C$  between  $A$  and  $B$  such that, with  $D = C/\mathfrak{m}C$ , we have either*

(i)  $\dim_k(D) \geq 4$ , or

(ii)  $D$  contains elements  $\alpha$  and  $\beta$  such that  $\{1, \alpha, \beta\}$  is linearly independent over  $k$  and  $\alpha^2 = \alpha\beta = \beta^2 = 0$ .

*Proof.* If (dr1) fails, we take  $C = B$ . Otherwise (dr2) fails, and we put  $C = A + \mathfrak{m}B$ . Since  $\dim_k \left(\frac{\mathfrak{m}B+A}{\mathfrak{m}^2B+A}\right) \geq 2$ , we can choose elements  $x, y \in \mathfrak{m}B$  such that the images of  $x$  and  $y$  in  $\frac{\mathfrak{m}B+A}{\mathfrak{m}^2B+A}$  are linearly independent. Since  $D := C/\mathfrak{m}C$  maps onto  $\frac{\mathfrak{m}B+A}{\mathfrak{m}^2B+A}$ , the images  $\alpha, \beta \in D$  of  $x, y$  are linearly independent, and they obviously satisfy the required equations.  $\square$

Now let's begin the proof of Theorem 3.5. We have an Artinian pair  $A \hookrightarrow B$ , where  $(A, \mathfrak{m}, k)$  is local and either (dr1) or (dr2) fails. We want to build indecomposable  $\mathbf{A}$ -modules  $V \hookrightarrow W$ , with  $W = B^{(n)}$ . By Lemmas 3.8 and 3.9, we can pass to the Artinian pair  $k \hookrightarrow D$  provided by Proposition 3.10. We fix a positive integer  $n$ . Our goal is to build an indecomposable  $(k \hookrightarrow D)$ -module  $(V \hookrightarrow D^{(n)})$  and, if  $k$  is infinite, a family  $\{(V_t \hookrightarrow D^{(n)})\}_{t \in T}$  of pairwise non-isomorphic indecomposable  $(k \hookrightarrow D)$ -modules, with  $|T| = |k|$ .

**3.11 Construction.** We describe a general construction, a modification of constructions found in [DR67, Wie89, ÇWW95]. Let  $n$  be a fixed positive

integer, and suppose we have chosen  $\alpha, \beta \in D$  with  $\{1, \alpha, \beta\}$  linearly independent over  $k$ . Let  $I$  be the  $n \times n$  identity matrix, and let  $H$  the  $n \times n$  nilpotent Jordan block in Lemma 3.1. For  $t \in k$ , we consider the  $n \times 2n$  matrix  $\Psi_t = [I \mid \alpha I + \beta(tI + H)]$ . Put  $W = D^{(n)}$ , viewed as columns, and let  $V_t$  be the  $k$ -subspace of  $W$  spanned by the columns of  $\Psi_t$ .

Suppose we have a morphism  $(V_t \hookrightarrow W) \longrightarrow (V_u \hookrightarrow W)$ , given by an  $n \times n$  matrix  $\varphi$  over  $D$ . The requirement that  $\varphi(V) \subseteq V$  says there is a  $2n \times 2n$  matrix  $\theta$  over  $k$  such that

$$(3.11.1) \quad \varphi \Psi_t = \Psi_u \theta.$$

Write  $\theta = \begin{bmatrix} A & B \\ P & Q \end{bmatrix}$ , where  $A, B, P, Q$  are  $n \times n$  blocks. Then (3.11.1) gives the following two equations:

$$(3.11.2) \quad \begin{aligned} \varphi &= A + \alpha P + \beta(uI + H)P \\ \alpha\varphi + \beta\varphi(tI + H) &= B + \alpha Q + \beta(uI + H)Q. \end{aligned}$$

Substituting the first equation into the second and combining terms, we get a mess:

$$(3.11.3) \quad \begin{aligned} -B + \alpha(A - Q) + \beta(tA - uQ + AH - HQ) + (\alpha + t\beta)(\alpha + u\beta)P \\ + \alpha\beta(HP + PH) + \beta^2(HPH + tHP + uPH) = 0. \end{aligned}$$

**3.12 Case.**  $D$  satisfies (ii). (There exist  $\alpha, \beta \in D$  such that  $\{1, \alpha, \beta\}$  is linearly independent and  $\alpha^2 = \alpha\beta = \beta^2 = 0$ .)

From (3.11.3) and the linear independence of  $\{1, \alpha, \beta\}$ , we get the equations

$$(3.12.1) \quad B = 0, \quad A = Q, \quad A((t - u)I + H) = HA.$$

If  $\varphi$  is an isomorphism, we see from (3.11.2) that  $A$  has to be invertible. If, in addition,  $t \neq u$ , the third equation in (3.12.1) gives a contradiction, since the left side is invertible and the right side is not. Thus  $(V_t \hookrightarrow W) \not\cong (V_u \hookrightarrow W)$  if  $t \neq u$ . To see that  $(V_t \hookrightarrow W)$  is indecomposable, we take  $u = t$  and suppose that  $\varphi$ , as above, is idempotent. Squaring the first equation in (3.11.2), and comparing “1” and “ $A$ ” terms, we see that  $A^2 = A$  and  $P = AP + PA$ . But equation (3.12.1) says that  $AH = HA$ , and it follows that  $A$  is in  $k[H]$ , which is a local ring. Therefore  $A = 0$  or  $I$ , and either possibility forces  $P = 0$ . Thus  $\varphi = 0$  or  $1$ , as desired. Thus we may take  $T = k$  in this case.  $\square$

**3.13 Assumptions.** Having dealt with the case (ii), we assume from now on that (i) holds, that is  $\dim_k(D) \geq 4$ .

**3.14 Case.**  *$D$  has an element  $\alpha$  such that  $\{1, \alpha, \alpha^2\}$  is linearly independent.*

Choose any element  $\beta \in D$  such that  $\{1, \alpha, \beta, \alpha^2\}$  is linearly independent. We let  $E$  be the set of elements  $t \in k$  for which  $\{1, \alpha, \beta, (\alpha + t\beta)^2\}$  is linearly independent. Then  $E$  is non-empty (since it contains 0). Also,  $E$  is open in the Zariski topology on  $k$  and therefore is cofinite in  $k$ . Moreover, if  $t \in E$ , the set  $E_t = \{u \in E \mid \{1, \alpha, \beta, (\alpha + t\beta)(\alpha + u\beta)\} \text{ is linearly independent}\}$  is non-empty and cofinite in  $E$ . We will show that  $(V_t \hookrightarrow W)$  is indecomposable for each  $t \in E$ , and that  $(V_t \hookrightarrow W) \not\cong (V_u \hookrightarrow W)$  if  $t$  and  $u$  are distinct elements of  $E$  with  $u \in E_t$ . Assuming this has been done we can complete the proof in this case as follows: Define an equivalence relation  $\sim$  on  $E$  by declaring that  $t \sim u$  if and only if  $(V_u \hookrightarrow D) \cong (V_t \hookrightarrow D)$ , and let  $T$  be a set of representatives. Then  $T \neq \emptyset$ , and  $(V_t \hookrightarrow W)$  is indecomposable for each  $t \in T$ .

Moreover, each equivalence class is finite and  $E$  is cofinite in  $k$ . Therefore, if  $k$  is infinite, it follows that  $|T| = |k|$ .

Suppose  $t \in E$  and  $u \in E_t$  (possibly with  $t = u$ ), and let  $\varphi: (V_t \hookrightarrow W) \longrightarrow (V_u \hookrightarrow W)$  be a homomorphism. With the notation of (3.11.1)–(3.11.3), one can show, by descending induction on  $i$  and  $j$ , that  $H^i P H^j = 0$  for all  $i, j = 0, \dots, n$ . (Cf. Exercise 3.28.) Therefore  $P = 0$ , and we again obtain equations (3.12.1). The rest of the proof proceeds exactly as in Case 3.12.  $\square$

The following lemma, whose proof is left as an exercise, is useful in treating the remaining case, when every element of  $D$  satisfies a monic quadratic equation over  $k$ :

**3.15 Lemma.** *Let  $\ell$  be a field, and let  $A$  be a finite-dimensional  $\ell$ -algebra with  $\dim_\ell(A) \geq 3$ . Assume that  $\{1, \alpha, \alpha^2\}$  is linearly dependent over  $\ell$  for every  $\alpha \in A$ . Write  $A = A_1 \times \cdots \times A_s$ , where each  $A_i$  is local, with maximal ideal  $\mathfrak{m}_i$ . Let  $\mathfrak{N} = \mathfrak{m}_1 \times \cdots \times \mathfrak{m}_s$ , the nilradical of  $A$ .*

(i) *If  $x \in \mathfrak{N}$ , then  $x^2 = 0$ .*

(ii) *There are at least  $|\ell|$  distinct rings between  $\ell$  and  $A$ .*

(iii) *If  $s \geq 2$ , then  $A_i/\mathfrak{m}_i = \ell$  for each  $i$ .*

(iv) *If  $s \geq 3$  then  $|\ell| = 2$*

$\square$

**3.16 Assumptions.** From now on, we assume that  $\{1, \alpha, \alpha^2\}$  is linearly dependent over  $k$  for each  $\alpha \in D$  (and that  $\dim_k(D) \geq 4$ ). We write  $D = D_1 \times \cdots \times D_s$ , where each  $D_i$  is local, with maximal ideal  $\mathfrak{m}_i$ ; we let  $\mathfrak{N} = \mathfrak{m}_1 \times \cdots \times \mathfrak{m}_s$ , the nilradical of  $D$ .

**3.17 Case.**  $\dim_k(\mathfrak{N}) \geq 2$ 

Choose  $\alpha, \beta \in \mathfrak{N}$  so that  $\{1, \alpha, \beta\}$  is linearly independent. Then  $\alpha^2 = \beta^2 = 0$  by Lemma 3.15. If  $\{1, \alpha, \beta, \alpha\beta\}$  is linearly independent, we can use the mess (3.11.3) to complete the proof. Otherwise, we can write  $\alpha\beta = a + b\alpha + c\beta$  with  $a, b, c \in k$ . Multiplying this equation first by  $\alpha$  and then by  $\beta$ , we learn that  $\alpha\beta = 0$ , and we are in Case 3.12.  $\square$

**3.18 Assumption.** We assume from now on that  $\dim_k(\mathfrak{N}) \leq 1$ .

From Lemma 3.15 we see that  $s$  (the number of components) cannot be 2. Also, if  $s = 3$ , then, after renumbering if necessary, we have  $\mathfrak{N} = \mathfrak{m}_1 \times 0 \times 0$  with  $\mathfrak{m}_1 \neq 0$ . Now put  $\alpha = (x, 1, 0)$ , where  $x$  is a non-zero element of  $\mathfrak{m}_1$ , and check that  $\{1, \alpha, \alpha^2\}$  is linearly independent, contradicting Assumption 3.16. We have proved that either  $s = 1$  or  $s \geq 4$ .

**3.19 Case.**  $s = 1$ . (*D is local.*)

By Assumptions 3.13 and 3.18,  $K := D/\mathfrak{N}$  must have degree at least three over  $k$ . On the other hand, Assumption 3.16 implies that each element of  $K$  has degree at most 2 over  $k$ . Therefore  $K/k$  is not separable,  $\text{char}(k) = 2$ ,  $\alpha^2 \in k$  for each  $\alpha \in K$ , and  $[K : k] \geq 4$ . Now choose two elements  $\alpha, \beta \in K$  such that  $[k(\alpha, \beta) : k] = 4$ . By Lemma 3.9 we can safely pass to the Artinian pair  $(k, K)$  and build our modules there; for compatibility with the notation in Construction 3.11, we rename  $K$  and call it  $D$ . Now we have  $\alpha, \beta \in D$  such that  $\{1, \alpha, \beta, \alpha\beta\}$  is linearly independent and both  $\alpha^2$  and  $\beta^2$  are in  $k$ . If, now,  $\varphi: (V_t \hookrightarrow W) \longrightarrow (V_u \hookrightarrow W)$  is a morphism, the mess (3.11.3)

provides the following equations:

$$(3.19.1) \quad \begin{aligned} B &= (\alpha^2 + tu\beta^2)P + \beta^2(HPH + tHP + uPH), & A &= Q, \\ A((t-u)I + H) &= HA, & (t+u)P + HP + PH &= 0. \end{aligned}$$

Suppose  $t \neq u$ . Then  $t+u \neq 0$  (characteristic 2), and the fourth equation shows, via a descending induction argument as in Case 3.14, that  $P = 0$ . (Cf. Exercise 3.28.) Now the third equation shows, as in Case 3.12, that  $\varphi$  is not an isomorphism.

Now suppose  $t = u$  and  $\varphi^2 = \varphi$ . Using the third and fourth equations of (3.19.1), the fact that  $\text{char}(k) = 2$ , and Lemma 3.1, we see that both  $A$  and  $P$  are in  $k[H]$ . In particular,  $A, P$  and  $H$  commute, and, since we are in characteristic two, we can square both sides of (3.11.2) painlessly. Equating  $\varphi$  and  $\varphi^2$ , we see that  $P = 0$  and  $A = A^2$ . Since  $k[H]$  is local,  $A = 0$  or  $I$ .  $\square$

One case remains:

### 3.20 Case. $s \geq 4$ .

By Lemma 3.15,  $|k| = 2$  and  $D_i/\mathfrak{m}_i = k$  for each  $i$ . By Lemma 3.9 we can forget about the radical and assume that  $D = k \times \cdots \times k$  (at least 4 components). Alas, this case does not yield to our general construction, but E. C. Dade's construction [Dad63] saves the day. (Dade works in greater generality, but the main idea is visible in the computation that follows. The key issue is that  $D$  has at least 4 components.)

Put  $W = D^{(n)}$ , and let  $V$  be the  $k$ -subspace of  $W$  consisting of all elements  $(x, y, x+y, x+Hy, x, \dots, x)$ , where  $x$  and  $y$  range over  $k^{(n)}$ . (Again,  $H$  is the nilpotent Jordan block with 1's on the superdiagonal.) Clearly  $DW = V$ . To see that  $(V \hookrightarrow W)$  is indecomposable, suppose  $\varphi$  is an endo-

morphism of  $(V \hookrightarrow W)$ , that is, a  $D$ -endomorphism of  $W$  carrying  $V$  into  $V$ . We write  $\varphi = (\alpha, \beta, \gamma, \delta, \varepsilon_5, \dots, \varepsilon_s)$ , where each component is an  $n \times n$  matrix over  $k$ . Since  $\varphi((x, 0, x, x, x, \dots, x))$  and  $\varphi((0, y, y, Hy, 0, \dots, 0))$  are in  $V$ , there are matrices  $\sigma, \tau, \xi, \eta$  satisfying the following two equations for all  $x \in k^{(n)}$ :

$$\begin{aligned} (\alpha x, 0, \gamma x, \delta x, \varepsilon_5 x, \dots, \varepsilon_s x) &= (\sigma x, \tau x, (\sigma + \tau)x, (\sigma + H\tau)x, \sigma x, \dots, \sigma x) \\ (0, \beta y, \gamma y, \delta Hy, 0, \dots, 0) &= (\xi y, \eta y, (\xi + \eta)y, (\xi + H\eta)y, \xi y, \dots, \xi y) \end{aligned}$$

The first equation shows that  $\varphi = (\alpha, \alpha, \dots, \alpha)$ , and the second then shows that  $\alpha H = H\alpha$ . By Lemma 3.1  $\alpha \in k[H] \cong k[x]/(x^n)$ , which is a local ring. If now,  $\varphi^2 = \varphi$ , then  $\alpha^2 = \alpha$ , and hence  $\alpha = 0$  or  $I_n$ . This shows that  $(V \hookrightarrow W)$  is indecomposable and completes the proof of Theorem 3.5.  $\square$

We close this chapter with the following partial converse to Theorem 3.5. This is due to Drozd-Roĭter [DR67] and Green-Reiner [GR78] in the special case where the residue field  $A/\mathfrak{m}$  is finite. In this case they reduced to the situation where where  $A/\mathfrak{m} \longrightarrow B/\mathfrak{n}$  is an isomorphism for each maximal ideal  $\mathfrak{n}$  of  $B$ . In this situation they showed, via explicit matrix decompositions, that conditions (dr1) and (dr2) imply that  $\mathbf{A}$  has finite representation type. These matrix decompositions depend only on the fact that the residue fields of  $B$  are all equal to  $k$ , and not on the fact that  $k$  is finite. The generalization stated here is due to R. Wiegand [Wie89] and depends crucially on the matrix decompositions in [GR78].

**3.21 Theorem.** *Let  $\mathbf{A} = (A \hookrightarrow B)$  be an Artinian pair in which  $A$  is local, with maximal ideal  $\mathfrak{m}$  and residue field  $k$ . Assume that  $B$  is a principal ideal ring and either*

- (i) the field extension  $k \hookrightarrow B/\mathfrak{n}$  is separable for every maximal ideal  $\mathfrak{n}$  of  $B$ , or
- (ii)  $B$  is reduced (hence a direct product of fields).

If  $\mathbf{A}$  satisfies (dr1) and (dr2), then  $\mathbf{A}$  has finite representation type.

*Proof.* As in [GR78] we will reduce to the case where the residue fields of  $B$  are all equal to  $k$ . By (d1)  $B$  has at most three maximal ideals, and at most one of these has a residue field  $\ell$  properly extending  $k$ . Moreover,  $[\ell : k] \leq 3$ . Assuming  $\ell \neq k$ , we choose a primitive element  $\theta$  for  $\ell/k$ , let  $f \in A[T]$  be a monic polynomial reducing to the minimal polynomial for  $\theta$  over  $k$ , and pass to the Artinian pair  $\mathbf{A}' = (A' \hookrightarrow B')$ , where  $A' = A[T]/(f)$  and  $B' = B \otimes_A A' = B[T]/(f)$ . Each of the conditions (i), (ii) guarantees that  $B'$  is a principal ideal ring.

One checks that the Drozd-Roĭter conditions ascend to  $\mathbf{A}'$ , and finite representation type descends. (This is not difficult; the details are worked out in [Wie89].) If  $k(\theta)/k$  is a separable, non-Galois extension of degree 3, then  $B'$  has a residue field that is separable of degree 2 over  $k$ , and we simply repeat the construction. Thus it suffices to prove the theorem in the case where each residue field of  $B$  is equal to  $k$ . For this case, we appeal to the matrix decompositions in [GR78], which work perfectly well over any field.  $\square$

### §3 Exercises

**3.22 Exercise.** Let  $\mathfrak{m}$  be a maximal ideal of a Noetherian ring  $R$ , and assume that  $\mathfrak{m}$  is not a minimal prime ideal of  $R$ . Then  $\{\mathfrak{m}^t \mid t \geq 1\}$  is an infinite strictly descending chain of ideals.

**3.23 Exercise.** Let  $(R, \mathfrak{m}, k)$  be a commutative local Artinian ring, and assume  $k$  is infinite.

- (i) If  $\mathcal{G}$  is a set of pairwise non-isomorphic finitely generated  $R$ -modules, prove that  $|\mathcal{G}| \leq |k|$ .
- (ii) Suppose  $R$  is not a principal ideal ring. Modify the proof of Theorem 3.2 to show that for each  $n \geq 1$  there is a family  $\mathcal{G}_n$  of pairwise non-isomorphic indecomposable modules, all requiring exactly  $n$  generators, with  $|\mathcal{G}_n| = |k|$ .

**3.24 Exercise.** Prove Lemmas 3.8 and 3.9.

**3.25 Exercise.** Prove Lemma 3.15. (For the second assertion, suppose there are fewer than  $|\ell|$  intermediate rings. Mimic the proof of the primitive element theorem to show that  $D = k[\alpha]$  for some  $\alpha$ .)

**3.26 Exercise.** With  $E$  and  $E_t$  as in 3.14, prove that  $|k - E| \leq 1$  and that  $|E - E_t| \leq 1$ .

**3.27 Exercise.** Let  $\mathbf{A} = (A \hookrightarrow B)$  be an Artinian pair, and let  $C_1$  and  $C_2$  be distinct rings between  $A$  and  $B$ . Prove that the  $\mathbf{A}$ -modules  $(C_1 \hookrightarrow B)$  and  $(C_2 \hookrightarrow B)$  are not isomorphic.

**3.28 Exercise.** Work out the details of the descending induction arguments in Case 3.14 and Case 3.19. (In Case 3.14, assuming  $H^{i+1}\gamma H^j = 0$  and  $H^i\gamma H^{j+1} = 0$ , multiply the mess (3.11.3) by  $H^i$  on the left and  $H^j$  on the right. In Case 3.19, use the fourth equation in (3.19.1) and do the same thing.)

# 4

## *Dimension one*

In this chapter we give necessary and sufficient conditions for a one-dimensional local ring to have finite Cohen-Macaulay type. In the main case of interest, where the completion  $\widehat{R}$  is reduced, these conditions are simply the liftings of the Drozd-Roĭter conditions (dr1) and (dr2) of Chapter 3. Necessity of these conditions follows easily from Theorem 3.5. To prove that they are sufficient, we will reduce the problem to consideration of some special cases, where we can appeal to the matrix decompositions of Green and Reiner [GR78] and, in characteristic two, Çimen [Çim94, Çim98].

Throughout this chapter  $(R, \mathfrak{m}, k)$  is a one-dimensional local ring (with maximal ideal  $\mathfrak{m}$  and residue field  $k$ ). Let  $K$  denote the total quotient ring  $\{\text{non-zero-divisors}\}^{-1}R$  and  $\overline{R}$  the integral closure of  $R$  in  $K$ . If  $R$  is reduced (hence CM), then  $\overline{R} = \overline{R/\mathfrak{p}_1} \times \cdots \times \overline{R/\mathfrak{p}_s}$ , where the  $\mathfrak{p}_i$  are the minimal prime ideals of  $R$ , and each ring  $\overline{R/\mathfrak{p}_i}$  is a semilocal principal ideal domain.

When  $R$  is CM, a finitely generated  $R$ -module  $M$  is MCM if and only if it is torsion-free, that is, the torsion submodule is zero.

We say that a finitely generated  $R$ -module  $M$  has *constant rank*  $n$  provided  $K \otimes_R M \cong K^{(n)}$ . If  $R$  is CM, then  $K = R_{\mathfrak{p}_1} \times \cdots \times R_{\mathfrak{p}_s}$ ; hence  $M$  has constant rank if and only if  $M_{\mathfrak{p}} \cong R_{\mathfrak{p}}^{(n)}$  for each minimal prime ideal  $\mathfrak{p}$ . (If  $R$  is *not* CM, then  $K = R$ , so free modules are the only modules with constant rank.)

The main result in this chapter is Theorem 4.10, which states that a one-dimensional local ring  $(R, \mathfrak{m}, k)$ , with reduced completion  $\widehat{R}$ , has finite CM type if and only if  $R$  satisfies the following two conditions:

(DR1)  $\mu_R(\bar{R}) \leq 3$ , and

(DR2)  $\frac{\mathfrak{m}_{\bar{R}} + R}{R}$  is a cyclic  $R$ -module.

The first condition just says that the multiplicity of  $R$  is at most three (cf. Theorem A.30). When the multiplicity is three we have to consider the second condition. One can check, for example, that  $k[[t^3, t^5]]$  satisfies (DR2) but that  $k[[t^3, t^7]]$  does not.

The case where the completion is not reduced is dealt with separately, in Theorem 4.16. In particular, we find (Corollary 4.17) that a one-dimensional local ring  $R$  has finite CM type if and only if its completion does. The analogous statement fails badly in higher dimension; cf. Chapter 10. Furthermore, Proposition 4.15 shows that if a one-dimensional CM local ring has finite CM type, then its completion is reduced; in particular  $R$  is an isolated singularity, which property will appear again in Chapter 7. We also treat the case of multiplicity two directly, without any reducedness assumption.

As a look ahead to later chapters, in §3 we discuss the alternative classification of finite CM type in dimension one due to Greuel and Knörrer in terms of the ADE hypersurface singularities.

## §1 Necessity of the Drozd-Roĭter conditions

Looking ahead to Chapter 16, we work in a somewhat more general context than is strictly required for Theorem 4.10. In particular, we will not assume that  $R$  is reduced, and  $\bar{R}$  will be replaced by a more general extension ring  $S$ . By a *finite birational extension* of  $R$  we mean a ring  $S$  between  $R$  and its total quotient ring  $K$  such that  $S$  is finitely generated as an  $R$ -module.

**4.1 Construction.** Let  $(R, \mathfrak{m}, k)$  be a CM local ring of dimension one, and let  $S$  be a finite birational extension of  $R$ . Put  $\mathfrak{c} = (R :_R S)$ , the *conductor* of  $S$  into  $R$ . This is the largest common ideal of  $R$  and  $S$ . Set  $A = R/\mathfrak{c}$  and  $B = S/\mathfrak{c}$ . Then the *conductor square* of  $R \hookrightarrow S$

$$(4.1.1) \quad \begin{array}{ccc} R & \hookrightarrow & S \\ \downarrow & & \downarrow \pi \\ A & \hookrightarrow & B \end{array}$$

is a pullback diagram, that is,  $R = \pi^{-1}(A)$ . Since  $S$  is a module-finite extension of  $R$  contained in the total quotient ring  $K$ , the conductor contains a non-zerodivisor (clear denominators), so that the bottom line  $\mathbf{A} = (A \hookrightarrow B)$  is an Artinian pair in the sense of Chapter 3.

Suppose that  $M$  is a MCM  $R$ -module. Then  $M$  is torsion-free, so the natural map  $M \rightarrow K \otimes_R M$  is injective. Let  $SM$  be the  $S$ -submodule of  $K \otimes_R M$  generated by the image of  $M$ ; equivalently,  $SM = (S \otimes_R M)/\text{torsion}$ . If we furthermore assume that  $SM$  is a projective  $S$ -module, then the inclusion  $M/\mathfrak{c}M \hookrightarrow SM/\mathfrak{c}M$  gives a module over the Artinian pair  $A \hookrightarrow B$ .

In the special case where  $S$  is the integral closure  $\overline{R}$ , the situation clarifies. Since  $\overline{R}$  is a direct product of semilocal principal ideal domains, and  $\overline{R}M$  is torsion-free for any MCM  $R$ -module  $M$ , it follows that  $\overline{R}M$  is  $\overline{R}$ -projective. Thus  $M/\mathfrak{c}M \hookrightarrow \overline{R}M/\mathfrak{c}M$  is automatically a module over the Artinian pair  $R/\mathfrak{c} \hookrightarrow \overline{R}/\mathfrak{c}$ . We dignify this special case with the notation  $R_{\text{art}} = (R/\mathfrak{c} \hookrightarrow \overline{R}/\mathfrak{c})$  and  $M_{\text{art}} = (M/\mathfrak{c}M \hookrightarrow \overline{R}M/\mathfrak{c}M)$ .

Now return to the case of a general finite birational extension  $S$ , and let  $V \hookrightarrow W$  be a module over the Artinian pair  $\mathbf{A} = (A \hookrightarrow B) = (R/\mathfrak{c} \hookrightarrow S/\mathfrak{c})$ . Assume that there exists a finitely generated projective  $S$ -module  $P$  such that  $W \cong$

$P/cP$ . (This is a real restriction; see the comments below.) We can then define an  $R$ -module  $M$  by a similar pullback diagram

$$(4.1.2) \quad \begin{array}{ccc} M & \hookrightarrow & P \\ \downarrow & & \downarrow \tau \\ V & \hookrightarrow & W \end{array}$$

so that  $M = \tau^{-1}(V)$ . Using the fact that  $BV = W$ , one can check that  $SM = P$ , so that in particular  $M$  is a MCM  $R$ -module. Moreover,  $M/cM = V$  and  $SM/cM = W$ , so that two non-isomorphic  $\mathbf{A}$ -modules that are both liftable have non-isomorphic liftings.

If in particular  $V \hookrightarrow W$  is an  $\mathbf{A}$ -module of constant rank, so that  $W \cong B^{(n)}$  for some  $n$ , then there is clearly a projective  $S$ -module  $P$  such that  $P/cP \cong W$ , namely  $P = S^{(n)}$ . Furthermore, in this case  $M$  has constant rank  $n$  over  $R$ . It follows that every  $\mathbf{A}$ -module of constant rank lifts to a MCM  $R$ -module of constant rank. Moreover, every  $\mathbf{A}$ -module is a direct summand of one of constant rank, so is a direct summand of a module extended from  $R$ .

By analogy with the terminology “weakly liftable” of [ADS93], we say that a module  $V \hookrightarrow W$  over the Artinian pair  $\mathbf{A} = R/c \hookrightarrow S/c$  is *weakly extended* (from  $R$ ) if there exists a MCM  $R$ -module  $M$  such that  $V \hookrightarrow W$  is a direct summand of the  $\mathbf{A}$ -module  $M/cM \hookrightarrow SM/cM$ . The discussion above shows that every  $\mathbf{A}$ -module is weakly extended from  $R$ .

Now we lift the Drozd-Roĭter conditions up to the finite birational extension  $R \hookrightarrow S$ .

**4.2 Theorem.** *Let  $(R, \mathfrak{m}, k)$  be a local ring of dimension one, and let  $S$  be a finite birational extension of  $R$ . Assume that either*

(i)  $\mu_R(S) \geq 4$ , or

(ii)  $\mu_R\left(\frac{mS+R}{R}\right) \geq 2$ .

Then  $R$  has infinite Cohen-Macaulay type. Moreover, given an arbitrary positive integer  $n$ , there is an indecomposable MCM  $R$ -module  $M$  of constant rank  $n$ ; if  $k$  is infinite, there are at least  $|k|$  pairwise non-isomorphic indecomposable MCM  $R$ -modules of constant rank  $n$ .

**4.3 Remark.** With  $R$  as in Theorem 4.2 and with  $k$  infinite, there are at most  $|k|$  isomorphism classes of  $R$ -modules of constant rank. To see this, we note that there are at most  $|k|$  isomorphism classes of finite-length modules and that every module of finite length has cardinality at most  $|k|$ . Given an arbitrary MCM  $R$ -module  $M$  of constant rank  $n$ , one can build an exact sequence

$$0 \longrightarrow T \longrightarrow M \longrightarrow R^{(n)} \longrightarrow U \longrightarrow 0,$$

in which both  $T$  and  $U$  have finite length. Let  $W$  be the kernel of  $R^{(n)} \longrightarrow U$  (and the cokernel of  $T \longrightarrow M$ ). Since  $|U| \leq |k|$ , we see that  $|\mathrm{Hom}_R(R^{(n)}, U)| \leq |k|$ . Since there are at most  $|k|$  possibilities for  $U$ , we see that there are at most  $|k|^2 = |k|$  possibilities for  $W$ . Since there are at most  $|k|$  possibilities for  $T$ , and since  $|\mathrm{Ext}_R^1(W, T)| \leq |k|$ , we see that there are at most  $|k|$  possibilities for  $M$ .

*Proof of Theorem 4.2.* The assumptions imply immediately that either (dr1) or (dr2) of Theorem 3.5 fails for the Artinian pair  $\mathbf{A} = (R/\mathfrak{c} \twoheadrightarrow S/\mathfrak{c})$ . Therefore there exist indecomposable  $\mathbf{A}$ -modules of arbitrary constant rank  $n$ , in fact,  $|k|$  of them if  $k$  is infinite. Each of these pulls back to  $R$ , so that there exist the same number of MCM  $R$ -modules of constant rank  $n$  for each  $n \geq 1$ .

Furthermore these MCM modules are pairwise non-isomorphic. Finally, we must show that if  $V \hookrightarrow W$  is indecomposable and  $M$  is a lifting to  $R$ , then  $M$  is indecomposable as well. Suppose  $M \cong X \oplus Y$ . Then  $SM = SX \oplus SY$ , and it follows that  $(V \hookrightarrow W)$  is the direct sum of the  $\mathbf{A}$ -modules  $(X/cX \hookrightarrow SX/cX)$  and  $(Y/cY \hookrightarrow SY/cY)$ . Therefore either  $X/cX = 0$  or  $Y/cY = 0$ . By NAK, either  $X = 0$  or  $Y = 0$ .  $\square$

The requisite extension  $S$  of Theorem 4.2 always exists if  $R$  is CM of multiplicity at least 4, as we now show.

**4.4 Proposition.** *Let  $(R, \mathfrak{m})$  be a one-dimensional CM local ring and set  $e = e(R)$ , the multiplicity of  $R$ . (See Appendix A §2.) Then  $R$  has a finite birational extension  $S$  requiring  $e$  generators as an  $R$ -module.*

*Proof.* Let  $K$  again be the total quotient ring of  $R$ . Let  $S_n = (\mathfrak{m}^n :_K \mathfrak{m}^n)$  for  $n \geq 1$ , and put  $S = \bigcup_n S_n$ . To see that this works, we may harmlessly assume that  $k$  is infinite. (This is relatively standard, but see Theorem 10.13 for the details on extending the residue field.) Let  $Rf \subseteq \mathfrak{m}$  be a principal reduction of  $\mathfrak{m}$ . Choose  $n$  so large that

(a)  $\mathfrak{m}^{i+1} = f\mathfrak{m}^i$  for  $i \geq n$ , and

(b)  $\mu_R(\mathfrak{m}^i) = e(R)$  for  $i \geq n$ .

Since  $f$  is a non-zerodivisor (as  $R$  is CM), it follows from (a) that  $S = S_n$ . We claim that  $Sf^n = \mathfrak{m}^n$ . We have  $Sf^n = S_n f^n \subseteq \mathfrak{m}^n$ . For the reverse inclusion, let  $\alpha \in \mathfrak{m}^n$ . Then  $\frac{\alpha}{f^n} \mathfrak{m}^n \subseteq \frac{1}{f^n} \mathfrak{m}^{2n} = \frac{1}{f^n} f^n \mathfrak{m}^n = \mathfrak{m}^n$ . This shows that  $\frac{\alpha}{f^n} \in S_n$ , and the claim follows. Therefore  $S \cong \mathfrak{m}^n$  (as  $R$ -modules), and now (b) implies that  $\mu(S) = e(R)$ .  $\square$

**4.5 Remark.** Observe that the proof of this Proposition shows more: for any one-dimensional CM local ring  $R$  and any ideal  $I$  of  $R$  containing a non-zero-divisor, there exists  $n \geq 1$  such that  $I^n$  is projective as a module over its endomorphism ring  $S = \text{End}_R(I^n)$ , which is a finite birational extension of  $R$ . (Ideals projective over their endomorphism ring are called *stable* in [Lip71] and [SV74].) Since  $S$  is semilocal,  $I^n$  is isomorphic to  $S$  as an  $S$ -module, whence as an  $R$ -module. Furthermore,  $n$  may be taken to be the least integer such that  $\mu_R(I^n)$  achieves its stable value. Sally and Vasconcelos show in [SV74, Theorem 2.5] that this  $n$  is at most  $\max\{1, e(R) - 1\}$ , where  $e(R)$  is the multiplicity of  $R$ . This will be useful in Theorem 4.18 below.

## §2 Sufficiency of the Drozd-Roïter conditions

In this section we will prove, modulo the matrix calculations of Green and Reiner [GR78] and Çimen [Çim94, Çim98], that the Drozd-Roïter conditions imply finite CM type. Recall that a local ring  $(R, \mathfrak{m})$  is said to be *analytically unramified* provided its completion  $\hat{R}$  is reduced. The next result gives an equivalent condition—finiteness of the integral closure—for one-dimensional CM local rings.

**4.6 Theorem** ([Kru30]). *Let  $(R, \mathfrak{m})$  be a local ring, and let  $\overline{R}$  be the integral closure of  $R$  in its total quotient ring.*

(i) ([Nag58]) *If  $R$  is analytically unramified, then  $\overline{R}$  is finitely generated as an  $R$ -module.*

(ii) ([Kru30]) *Suppose  $R$  is one-dimensional and CM. If  $\overline{R}$  is finitely generated as an  $R$ -module then  $R$  is analytically unramified.*

*Proof.* See [Mat89, p. 263] or [HS06, 4.6.2] for a proof of (i). With the assumptions in (ii), we'll show first that  $R$  is reduced. Suppose  $x$  is a non-zero nilpotent element of  $R$  and  $t$  a non-zero-divisor in  $\mathfrak{m}$ . Then

$$R \frac{x}{t} \subset R \frac{x}{t^2} \subset R \frac{x}{t^3} \subset \dots$$

is an infinite strictly ascending chain of  $R$ -submodules of  $\overline{R}$ , contradicting finiteness of  $\overline{R}$ . Now assume that  $R$  is reduced and let  $\mathfrak{p}_1, \dots, \mathfrak{p}_s$  be the minimal prime ideals of  $R$ . There are inclusions

$$R \hookrightarrow R/\mathfrak{p}_1 \times \dots \times R/\mathfrak{p}_s \hookrightarrow \overline{R/\mathfrak{p}_1} \times \dots \times \overline{R/\mathfrak{p}_s} = \overline{R}.$$

Each of the rings  $\overline{R/\mathfrak{p}_i}$  is a semilocal principal ideal domain. Since  $\overline{R}$  is a finitely generated  $R$ -module, the  $\mathfrak{m}$ -adic completion of  $\overline{R}$  is the product of the completions of the localizations of the  $\overline{R/\mathfrak{p}_i}$  at their maximal ideals. In particular, the  $\mathfrak{m}$ -adic completion of  $\overline{R}$  is a direct product of discrete valuation rings. The flatness of  $\widehat{R}$  implies that  $\widehat{R}$  is contained in the  $\mathfrak{m}$ -adic completion of  $\overline{R}$ , hence is reduced.  $\square$

In the proof of part (ii) of the following proposition we encounter the subtlety mentioned in Construction 4.1: not every projective module over  $B$  is of the form  $P/cP$  for a projective  $S$ -module. This is because  $\overline{R}$  might not be a direct product of local rings. For example, the integral closure  $\overline{R}$

of the ring  $R = \mathbb{C}[x, y]_{(x, y)} / (y^2 - x^3 - x^2)$  has two maximal ideals (see Exercise 4.22), and so  $\overline{R}/\mathfrak{c}$  is a direct product  $B_1 \times B_2$  of two local rings. Obviously  $B_1 \times 0$  does not come from a projective  $\overline{R}$ -module and hence cannot be the second component of an  $R_{\text{art}}$ -module of the form  $M_{\text{art}}$ . The reader may recognize that exactly the same phenomenon gives rise to modules over the completion  $\widehat{R}$  that don't come from  $R$ -modules as we saw in Chapter 2.

Recall that we use the notation  $M_1 \mid M_2$ , introduced in Chapter 1, to indicate that  $M_1$  is isomorphic to a direct summand of  $M_2$ .

**4.7 Proposition.** *Let  $(R, \mathfrak{m}, k)$  be an analytically unramified local ring of dimension one, and assume  $R \neq \overline{R}$ . Let  $R_{\text{art}}$  be the Artinian pair  $R/\mathfrak{c} \rightarrow \overline{R}/\mathfrak{c}$ .*

- (i) *The functor  $M \rightsquigarrow M_{\text{art}} = (M/\mathfrak{c}M \hookrightarrow \overline{R}M/\mathfrak{c}M)$ , for  $M$  a MCM  $R$ -module, is injective on isomorphism classes.*
- (ii) *If  $M_1$  and  $M_2$  are MCM  $R$ -modules, then  $M_1 \mid M_2$  if and only if  $(M_1)_{\text{art}} \mid (M_2)_{\text{art}}$ .*
- (iii) *The ring  $R$  has finite CM type if and only if the Artinian pair  $R_{\text{art}}$  has finite representation type.*

*Proof.* (i) First observe that  $M \rightsquigarrow M_{\text{art}}$  is indeed well-defined: since  $\overline{R}$  is a direct product of principal ideal rings,  $\overline{R}M$  is a projective  $\overline{R}$ -module, so  $\overline{R}M/\mathfrak{c}M$  is a projective  $\overline{R}/\mathfrak{c}$ -module. Thus  $M_{\text{art}}$  is a module over  $R_{\text{art}}$ . Let  $M_1$  and  $M_2$  be MCM  $R$ -modules, and suppose that  $(M_1)_{\text{art}} \cong (M_2)_{\text{art}}$ . Write  $(M_i)_{\text{art}} = (V_i \hookrightarrow W_i)$ , and choose an isomorphism  $\varphi: W_1 \rightarrow W_2$  such that  $\varphi(V_1) = V_2$ . Since  $\overline{R}M_1$  is  $\overline{R}$ -projective, we can lift  $\varphi$  to an  $\overline{R}$ -homomorphism

$\psi: \overline{R}M_1 \longrightarrow \overline{R}M_2$  carrying  $M_1$  into  $M_2$ .

Since  $\mathfrak{c} \subseteq \mathfrak{m}$ , the induced  $R$ -homomorphism  $M_1 \longrightarrow M_2$  is surjective, by Nakayama's Lemma. (Here we need the assumption that  $R \neq \overline{R}$ .) Similarly,  $M_2$  maps onto  $M_1$ , and it follows that  $M_1 \cong M_2$  (see Exercise 4.25).

(ii) The “only if” direction is clear. For the converse, suppose there is an  $R_{\text{art}}$ -module  $\mathfrak{X} = (V \hookrightarrow W)$  such that  $(M_1)_{\text{art}} \oplus \mathfrak{X} \cong (M_2)_{\text{art}}$ . Write  $\overline{R} = D_1 \times \cdots \times D_s$ , where each  $D_i$  is a semilocal principal ideal domain. Put  $B_i = D_i/\mathfrak{c}D_i$ , so that  $\overline{R}/\mathfrak{c} = B_1 \times \cdots \times B_s$ . Since  $\overline{R}M_1$ , and  $\overline{R}M_2$  are projective  $\overline{R}$ -modules, there are non-negative integers  $e_i, f_i$  such that  $\overline{R}M_1 \cong \prod_i D_i^{(e_i)}$  and  $\overline{R}M_2 \cong \prod_i D_i^{(f_i)}$ . Then  $\overline{R}M_1/\mathfrak{c}M_1 \cong \prod_i B_i^{(e_i)}$ , similarly  $\overline{R}M_2/\mathfrak{c}M_2 \cong \prod_i B_i^{(f_i)}$ , and  $W = \prod_i B_i^{(f_i - e_i)}$ . Letting  $P = \prod_i D_i^{(f_i - e_i)}$ , we see that  $W \cong P/\mathfrak{c}P$ . As discussed in Construction 4.1, it follows that there is a MCM  $R$ -module  $N$  such that  $N_{\text{art}} \cong \mathfrak{X}$ . We see from (i) that  $M_1 \oplus N \cong M_2$ .

(iii) Suppose  $R_{\text{art}}$  has finite representation type, and let  $\mathbf{X}_1, \dots, \mathbf{X}_t$  be a full set of representatives for the non-isomorphic indecomposable  $R_{\text{art}}$ -modules. Given a MCM  $R$ -module  $M$ , write  $M_{\text{art}} \cong \mathbf{X}_1^{(n_1)} \oplus \cdots \oplus \mathbf{X}_t^{(n_t)}$ , and put  $j([M]) = (n_1, \dots, n_t)$ . By KRS (Theorem 3.4),  $j$  is a well-defined function from the set of isomorphism classes of MCM  $R$ -modules to  $\mathbb{N}_0^{(t)}$ , where  $\mathbb{N}_0$

is the set of non-negative integers. Moreover,  $j$  is injective, by (i). Letting  $\Sigma$  be the image of  $j$ , we see, using (ii), that  $M$  is indecomposable if and only if  $j[M]$  is a minimal non-zero element of  $\Sigma$  with respect to the product ordering. Dickson's Lemma (Exercise 2.21) says that every antichain in  $\mathbb{N}_0^{(t)}$  is finite. In particular,  $\Sigma$  has only finitely many minimal elements, and  $R$  has finite CM type.

We leave the proof of the converse (which will not be needed here) as an exercise.  $\square$

**4.8 Remark.** It's worth observing that the proof of Proposition 4.7 uses KRS only over  $R_{\text{art}}$ , not over  $R$  (which is not assumed to be Henselian). In fact, if the completion  $\widehat{R}$  is reduced, then  $(\widehat{R})_{\text{art}} = R_{\text{art}}$ . Indeed, the bottom row  $R/\mathfrak{c} \hookrightarrow \overline{R}/\mathfrak{c}$  of the conductor square for  $R$  is unaffected by completion since  $\overline{R}/\mathfrak{c}$  has finite length. Therefore the  $\mathfrak{m}$ -adic completion of the conductor square for  $R$  is

$$(4.8.1) \quad \begin{array}{ccc} \widehat{R} & \hookrightarrow & \widehat{R} \otimes_R \overline{R} \\ \downarrow & & \downarrow \widehat{\pi} \\ R/\mathfrak{c} & \hookrightarrow & \overline{R}/\mathfrak{c} \end{array}$$

which is still a pullback diagram by flatness of the completion. Note that  $\widehat{R} \otimes_R \overline{R}$  is the integral closure of  $\widehat{R}$ . No non-zero ideal of  $\overline{R}/\mathfrak{c}$  is contained in  $R/\mathfrak{c}$ , so  $\ker \widehat{\pi}$  is the largest ideal of  $\widehat{R} \otimes_R \overline{R}$  contained in  $\widehat{R}$ . Since also  $\ker \widehat{\pi}$  contains a non-zerodivisor,  $\ker \widehat{\pi}$  is the conductor for  $\widehat{R}$  and (4.8.1) is the conductor square for  $\widehat{R}$ .

In particular, this shows that an analytically unramified  $R$  has finite CM type if and only if  $\widehat{R}$  does. This is true as well in the case where  $\widehat{R}$  is not reduced, cf. Corollary 4.17 below.

Returning now to sufficiency of the Drozd-Roĭter conditions, we will need the following observation from Bass's "ubiquity" paper [Bas63, (7.2)]:

**4.9 Lemma** (Bass). *Let  $(R, \mathfrak{m})$  be a one-dimensional Gorenstein local ring. Let  $M$  be a MCM  $R$ -module with no non-zero free direct summand. Let  $E = \text{End}_R(\mathfrak{m})$ . Then  $E$  (viewed as multiplications) is a subring of  $\overline{R}$  which contains  $R$  properly, and  $M$  has an  $E$ -module structure that extends the action of  $R$  on  $M$ .*

*Proof.* The inclusion  $\text{Hom}_R(M, \mathfrak{m}) \rightarrow \text{Hom}_R(M, R)$  is bijective, since a surjective homomorphism  $M \rightarrow R$  would produce a non-trivial free summand of  $M$ . Now  $\text{Hom}_R(M, \mathfrak{m})$  is an  $E$ -module via the action of  $E$  on  $\mathfrak{m}$  by endomorphisms, and hence so is  $M^* = \text{Hom}_R(M, R)$ . Therefore  $M^{**}$  is also an  $E$ -module, and since the canonical map;  $M \rightarrow M^{**}$  is bijective (as  $R$  is Gorenstein and  $M$  is MCM),  $M$  is an  $E$ -module. The other assertions regarding  $E$  are left to the reader. (See Exercise 4.28. Note that the existence of the module  $M$  prevents  $R$  from being a discrete valuation ring.)  $\square$

Now we are ready for the main theorem of this chapter. We will not give a self-contained proof that the Drozd-Roĭter conditions imply finite CM type. Instead, we will reduce to a few special situations where the matrix decompositions of Green and Reiner [GR78] and Çimen [Çim94, Çim98] apply.

**4.10 Theorem.** *Let  $(R, \mathfrak{m}, k)$  be an analytically unramified local ring of dimension one. These are equivalent:*

- (i)  $R$  has finite CM type.

(ii)  $R$  satisfies both (DR1) and (DR2).

Let  $n$  be an arbitrary positive integer. If either (DR1) or (DR2) fails, there is an indecomposable MCM  $R$ -module of constant rank  $n$ ; moreover, if  $|k|$  is infinite, there are at least  $|k|$  pairwise non-isomorphic indecomposable MCM  $R$ -modules of constant rank  $n$ .

*Proof.* By Theorem 4.6,  $\overline{R}$  is a finite birational extension of  $R$ . The last statement of the theorem and the fact that (i)  $\implies$  (ii) now follow immediately from Theorem 4.2 with  $S = \overline{R}$ .

Assume now that (DR1) and (DR2) hold. Let  $A = R/\mathfrak{c}$  and  $B = \overline{R}/\mathfrak{c}$ , so that  $R_{\text{art}} = (A \hookrightarrow B)$ . Then  $R_{\text{art}}$  satisfies (dr1) and (dr2). By Proposition 4.7 it will suffice to prove that  $R_{\text{art}}$  has finite representation type. If every residue field of  $B$  is separable over  $k$ , then  $R_{\text{art}}$  has finite representation type by Theorem 3.21.

Now suppose that  $B$  has a residue field  $\ell = B/\mathfrak{n}$  that is not separable over  $k$ . By (dr1),  $\ell/k$  has degree 2 or 3, and  $\ell$  is the only residue field of  $B$  that is not equal to  $k$ .

**4.11 Case.**  $\ell/k$  is purely inseparable of degree 3.

If  $B$  is reduced (that is,  $R$  is *seminormal*), we can appeal to Theorem 3.21. Suppose now that  $B$  is *not* reduced. A careful computation of lengths (see Exercise 4.27) shows that  $R$  is Gorenstein, with exactly one ring  $S$  (the seminormalization of  $R$ ) strictly between  $R$  and  $\overline{R}$ . By Lemma 4.9,  $E := \text{End}_R(\mathfrak{m}) \supseteq S$ , and every non-free indecomposable MCM  $R$ -module is naturally an  $S$ -module. The Drozd-Roĭter conditions clearly

pass to the seminormal ring  $S$ , which therefore has finite Cohen-Macaulay type. It follows that  $R$  itself has finite Cohen-Macaulay type.

**4.12 Case.**  $\ell/k$  is purely inseparable of degree 2.

In this case, we appeal to Çimen's *tour de force* [Çim94],[Çim98], where he shows, by explicit matrix decompositions, that  $R_{\text{art}}$  has finite representation type.  $\square$

Let's insert here a few historical remarks. The conditions (DR1) and (DR2) were introduced by Drozd and Roĭter in a remarkable 1967 paper [DR67], where they classified the module-finite  $\mathbb{Z}$ -algebras having only finitely many indecomposable finitely generated torsion-free modules. Jacobinski [Jac67] obtained similar results at about the same time. The theorems of Drozd-Roĭter and Jacobinski imply the equivalence of (i) and (ii) in Theorem 4.10 for rings essentially module-finite over  $\mathbb{Z}$ . In the same paper they asserted the equivalence of (i) and (ii) in general. In 1978 Green and Reiner [GR78] verified the classification theorem of Drozd and Roĭter, giving more explicit details of the matrix decompositions needed to verify finite CM type. Their proof, like that of Drozd and Roĭter, depended crucially on arithmetic properties of algebraic number fields and thus did not provide immediate insight into the general problem. An important point here is that the matrix reductions of Green and Reiner work in arbitrary characteristics, as long as the integral closure  $\overline{R}$  has no residue field properly extending that of  $R$ .

In 1989 R. Wiegand [Wie89] proved necessity of the Drozd-Roĭter conditions (DR1) and (DR2) for a general one-dimensional local ring  $(R, \mathfrak{m}, k)$  and, via the separable descent argument in the proof of Theorem 3.21, suffi-

ciency under the assumption that every residue field of the integral closure  $\overline{R}$  is separable over  $k$ . By (DR1), this left only the case where  $k$  is imperfect of characteristic two or three. In [Wie94], he used the seminormality argument above to handle the case of characteristic three. Finally, in his 1994 Ph.D. dissertation [Çim94], N. Çimen solved the remaining case—characteristic two—by difficult matrix reductions. It is worth noting that Çimen’s matrix decompositions work in all characteristics and therefore confirm the computations done by Green and Reiner in 1978. The existence of  $|k|$  indecomposables of constant rank  $k$ , when  $|k|$  is infinite and (DR) fails, was proved by Karr and Wiegand [KW09] in 2009.

### §3 ADE singularities

Of course we have not really proved sufficiency of the Drozd-Roĭter conditions, since we have not presented all of the difficult matrix calculations of Green and Reiner [GR78] and Çimen [Çim94, Çim98]. If  $R$  contains the field of rational numbers, there is an alternate approach that uses the classification, which we present in Chapter 6, of the two-dimensional hypersurface singularities of finite Cohen-Macaulay type. First we recall the 1985 classification, by Greuel and Knörrer [GK85], of the complete, equicharacteristic-zero curve singularities of finite Cohen-Macaulay type. Suppose  $k$  is an algebraically closed field of characteristic different from 2, 3 or 5. The complete ADE (or *simple*) plane curve singularities over  $k$  are the rings  $k[[x, y]]/(f)$ , where  $f$  is one of the following polynomials:

$$(A_n): x^2 + y^{n+1}, \quad n \geq 1$$

$$(D_n): x^2y + y^{n-1}, \quad n \geq 4$$

$$(E_6): x^3 + y^4$$

$$(E_7): x^3 + xy^3$$

$$(E_8): x^3 + y^5$$

We will encounter these singularities again in Chapter 6. Here we will discuss briefly their role in the classification of one-dimensional rings of finite CM type. Greuel and Knörrer [GK85] proved that the ADE singularities are exactly the complete plane curve singularities of finite CM type in equicharacteristic zero. In fact, they showed much more, obtaining, essentially, the conclusion of Theorem 4.2 in this context:

**4.13 Theorem** (Greuel and Knörrer). *Let  $(R, \mathfrak{m}, k)$  be a one-dimensional reduced complete local ring containing  $\mathbb{Q}$ . Assume that  $k$  is algebraically closed.*

- (i)  *$R$  satisfies the Drozd-Roïter conditions if and only if  $R$  is a finite birational extension of an ADE singularity.*
- (ii) *Suppose that  $R$  has infinite CM type.*
  - (a) *There are infinitely many rings between  $R$  and its integral closure.*
  - (b) *For every  $n \geq 1$  there are infinitely many isomorphism classes of indecomposable MCM  $R$ -modules of constant rank  $n$ .*

Greuel and Knörrer used Jacobinski's computations [Jac67] to prove that ADE singularities have finite CM type. The fact that finite CM type

passes to finite birational extensions (in dimension one!) is recorded in Proposition 4.14 below. We note that (iia) can fail for infinite fields that are not algebraically closed. Suppose, for example, that  $\ell/k$  is a separable field extension of degree  $d > 3$ . Put  $R = k + x\ell[[x]]$ . Then  $\bar{R} = \ell[[x]]$  is minimally generated, as an  $R$ -module, by  $\{1, x, \dots, x^{d-1}\}$ . Theorem 4.10 implies that  $R$  has infinite CM type. There are, however, only finitely many rings between  $R$  and  $\bar{R}$ . Indeed, the conductor square (4.1.1) shows that the intermediate rings correspond bijectively to the intermediate fields between  $k$  and  $\ell$ .

In Chapter 8 we will use the classification of two-dimensional hypersurface rings of finite CM type to show that the one-dimensional ADE singularities have finite CM type (even in characteristic  $p$ , as long as  $p \geq 7$ ). Then, in Chapter 10, we will deduce that the Drozd-Roĭter conditions imply finite CM type for any one-dimensional local ring CM ring  $(R, \mathfrak{m}, k)$  containing a field, provided  $k$  is perfect and of characteristic  $\neq 2, 3, 5$ . Together with Greuel and Knörrer's result and the next proposition, this will give a different, slightly roundabout, proof that the Drozd-Roĭter conditions are sufficient for finite CM type in dimension one.

**4.14 Proposition.** *Let  $R$  and  $S$  be one-dimensional local rings, and suppose  $S$  is a finite birational extension of  $R$ .*

- (i) *If  $M$  and  $N$  are MCM  $S$ -modules, then  $\text{Hom}_R(M, N) = \text{Hom}_S(M, N)$ .*
- (ii) *Every MCM  $S$ -module is a MCM  $R$ -module.*
- (iii) *If  $M$  is a MCM  $S$ -module then  $M$  is indecomposable over  $S$  if and only if  $M$  is indecomposable over  $R$ .*

(iv) If  $R$  has finite CM type, so has  $S$ .

*Proof.* We may assume that  $R$  is CM, else  $R = S$ , and everything is boring.

(i) We need only verify that  $\text{Hom}_R(M, N) \subseteq \text{Hom}_S(M, N)$ . Let  $\varphi: M \rightarrow N$  be an  $R$ -homomorphism. Given any  $s \in S$ , write  $s = r/t$ , where  $r \in R$  and  $t$  is a non-zerodivisor of  $R$ . Then, for any  $x \in M$ , we have  $t\varphi(sx) = \varphi(rx) = r\varphi(x) = ts\varphi(x)$ . Since  $N$  is torsion-free, we have  $\varphi(sx) = s\varphi(x)$ . Thus  $\varphi$  is  $S$ -linear.

(ii) If  $M$  is a MCM  $S$ -module, then  $M$  is finitely generated and torsion-free, hence MCM, over  $R$ .

(iii) is clear from (i) and the fact that  ${}_S M$  is indecomposable if and only if  $\text{Hom}_S(M, M)$  contains no idempotents. Finally, (iv) is clear from (iii), (ii) and the fact that by (i) non-isomorphic MCM  $S$ -modules are non-isomorphic over  $R$ .  $\square$

## §4 The analytically ramified case

Let  $(R, \mathfrak{m})$  be a local Noetherian ring of dimension one, let  $K$  be the total quotient ring  $\{\text{non-zerodivisors}\}^{-1}R$ , and let  $\overline{R}$  be the integral closure of  $R$  in  $K$ . Suppose  $\overline{R}$  is *not* finitely generated over  $R$ . Then, since algebra-finite integral extensions are module-finite, no finite subset of  $\overline{R}$  generates  $\overline{R}$  as an  $R$ -algebra, and we can build an infinite ascending chain of finitely generated  $R$ -subalgebras of  $\overline{R}$ . Each algebra in the chain is a maximal Cohen-Macaulay  $R$ -module, and it is easy to see (Exercise 4.30) that no two of the algebras are isomorphic as  $R$ -modules. Moreover, each of these algebras is isomorphic, as an  $R$ -module, to a faithful ideal of  $R$ . Therefore  $R$

has an infinite family of pairwise non-isomorphic faithful ideals. It follows (Exercise 4.31) that  $R$  has infinite CM type. Now Theorem 4.6 implies the following result:

**4.15 Proposition.** *Let  $(R, \mathfrak{m}, k)$  be a one-dimensional CM local ring with finite Cohen-Macaulay type. Then  $R$  is analytically unramified.  $\square$*

In particular, this proposition shows that  $R$  itself is reduced; equivalently,  $R$  is an isolated singularity:  $R_{\mathfrak{p}}$  is a regular local ring (a field!) for every non-maximal prime ideal  $\mathfrak{p}$ . See Theorem 7.12.

What if  $R$  is *not* Cohen-Macaulay? The next theorem and Theorem 4.10 provide the full classification of one-dimensional local rings of finite Cohen-Macaulay type. We will leave the proof as an exercise.

**4.16 Theorem** ([Wie94, Theorem 1]). *Let  $(R, \mathfrak{m})$  be a one-dimensional local ring, and let  $N$  be the nilradical of  $R$ . Then  $R$  has finite Cohen-Macaulay type if and only if*

(i)  $R/N$  has finite Cohen-Macaulay type, and

(ii)  $\mathfrak{m}^i \cap N = (0)$  for  $i \gg 0$ .  $\square$

For example,  $k[[x, y]]/(x^2, xy)$  has finite Cohen-Macaulay type, since  $(x)$  is the nilradical and  $(x, y)^2 \cap (x) = (0)$ . However  $k[[x, y]]/(x^3, x^2y)$  has infinite CM type: For each  $i \geq 1$ ,  $xy^{i-1}$  is a non-zero element of  $(x, y)^i \cap (x)$ .

**4.17 Corollary** ([Wie94, Corollary 2]). *Let  $(R, \mathfrak{m})$  be a one-dimensional local ring. Then  $R$  has finite CM type if and only if the  $\mathfrak{m}$ -adic completion  $\widehat{R}$  has finite CM type.  $\square$*

*Proof.* Suppose first that  $R$  is analytically unramified. Since the bottom lines of the conductor squares for  $R$  and for  $\widehat{R}$  are identical (Remark 4.8), it follows from (iii) of Proposition 4.7 that  $R$  has finite CM type if and only if  $\widehat{R}$  has finite CM type.

For the general case, let  $N$  be the nilradical of  $R$ . Suppose  $R$  has finite CM type. The CM ring  $R/N$  then has finite CM type by Theorem 4.16 and hence is analytically unramified by Proposition 4.15. It follows that  $\widehat{N}$  is the nilradical of  $\widehat{R}$ . By the first paragraph,  $\widehat{R}/\widehat{N}$  has finite CM type; moreover,  $\widehat{m}^i \cap \widehat{N} = (0)$  for  $i \gg 0$ . Therefore  $\widehat{R}$  has finite CM type. For the converse, assume that  $\widehat{R}$  has finite CM type. Since every MCM  $\widehat{R}/\widehat{N}$ -module is also a MCM  $\widehat{R}$ -module, we see that  $\widehat{R}/\widehat{N} = \widehat{R}/\widehat{N}$  has finite CM type. Since  $R/N$  is CM, so is  $\widehat{R}/\widehat{N}$ , and now Theorem 4.15 implies that  $\widehat{R}/\widehat{N}$  is reduced. By the first paragraph,  $R/N$  has finite CM type. Now  $\widehat{N}$  is contained in the nilradical of  $\widehat{R}$ , so Theorem 4.16 implies that  $\widehat{m}^i \cap \widehat{N} = (0)$  for  $i \gg 0$ . It follows that  $m^i \cap N = (0)$  for  $i \gg 0$ , and hence that  $R$  has finite CM type.  $\square$

It is interesting to note that the proof of the corollary does not depend on the characterization (Theorem 4.10) of one-dimensional analytically unramified local rings of finite CM type. We remark that in higher dimensions finite CM type does not always ascend to the completion (see Example 10.11).

## §5 Multiplicity two

Suppose  $(R, \mathfrak{m})$  is an analytically unramified one-dimensional local ring and that  $\dim_k(\overline{R}/\overline{\mathfrak{m}R}) = 2$ . One can show (cf. Exercise 4.29) that  $R$  auto-

matically satisfies (DR2) and therefore has finite CM type. Here we will give a direct proof of finite CM type in multiplicity two, using some results in Bass's "ubiquity" paper [Bas63]. We don't assume that  $\overline{R}$  is a finitely generated  $R$ -module.

We refer the reader to Appendix A, §2 for basic stuff on multiplicities, particularly for one-dimensional rings.

**4.18 Theorem.** *Let  $(R, \mathfrak{m}, k)$  be a one-dimensional Cohen-Macaulay local ring with  $e(R) = 2$ .*

- (i) *Every ideal of  $R$  is generated by at most two elements.*
- (ii) *Every ring  $S$  with  $R \subseteq S \subsetneq \overline{R}$  and finitely generated over  $R$  is local and Gorenstein. In particular  $R$  itself is Gorenstein.*
- (iii) *Every MCM  $R$ -module is isomorphic to a direct sum of ideals of  $R$ . In particular, every indecomposable MCM  $R$ -module has multiplicity at most 2 and is generated by at most 2 elements.*
- (iv) *The ring  $R$  has finite CM type if and only if  $R$  is analytically unramified.*

*Proof.* Item (i) follows from [Sal78, Chap. 3, Theorem 1.1] or [Gre82].

(ii) Let  $S$  be a module-finite  $R$ -algebra properly contained in  $\overline{R}$ . Every ideal  $I$  of  $S$  is isomorphic to an ideal of  $R$  (clear denominators) and hence is two-generated as an  $R$ -module; therefore  $I$  is generated by two elements as an ideal of  $S$ . Since the maximal ideal of  $S$  is two-generated, Exercise 4.33 guarantees that  $S$  is Gorenstein. Moreover, the multiplicity of  $S$  as a module over itself is two. If  $S$  is not local, then its multiplicity is

the sum of the multiplicities of its localizations at maximal ideals, so  $S$  is regular, contradicting  $S \neq \overline{R}$ .

(iii) Let  $M$  first be a faithful MCM  $R$ -module. As  $M$  is torsion-free, the map  $j: M \rightarrow K \otimes_R M$  is injective. Let  $H = \{t \in K \mid tj(M) \subseteq j(M)\}$ ; then  $M$  is naturally an  $H$ -module. Since  $M$  is faithful,  $H \hookrightarrow \text{Hom}_R(M, M)$ , and thus  $H$  is a module-finite extension of  $R$  contained in  $\overline{R}$ . Suppose first that  $H = \overline{R}$ . Then  $R$  is reduced by Lemma 4.6, and hence  $\overline{R}$  is a principal ideal ring. It follows from the structure theory for modules over a principal ideal ring that  $M$  has a copy of  $H$  as a direct summand, and of course  $H$  is isomorphic to an ideal of  $R$ . If  $H$  is properly contained in  $\overline{R}$ , then, since  $H/R$  has finite length, we can apply Lemma 4.9 repeatedly, eventually getting a copy of some subring of  $H$  as a direct summand of  $M$ . In either case, we see that  $M$  has a faithful ideal of  $R$  as a direct summand.

Suppose, now, that  $M$  is an arbitrary MCM  $R$ -module, and let  $I = (0 :_R M)$ . Then  $R/I$  embeds in a direct product of copies of  $M$  (one copy for each generator); therefore  $R/I$  has depth 1 and hence is a one-dimensional CM ring. Of course  $e(R) \leq 2$ , and, since  $M$  is a faithful MCM  $R/U$ -module,  $M$  has a non-zero ideal of  $R/I$  as a direct summand. To complete the proof, it will suffice to show that  $R/I$  is isomorphic to an ideal of  $R$ . By basic duality theory over the Gorenstein ring  $R$ , the type of  $R/I$  is equal to the number of generators  $\mu_R((R/I)^*)$  of its dual  $(R/I)^*$ . Since  $R/I$  is Gorenstein, this implies that  $(R/I)^*$  is cyclic. Choosing a surjection  $R^* \twoheadrightarrow (R/I)^*$  and dualizing again, we have (since  $R/I$  is MCM and  $R$  is Gorenstein)  $R/I \hookrightarrow R$  as desired.

(iv) The “only if” implication is Proposition 4.15. For the converse, we

assume that  $R$  is analytically unramified, so that  $\overline{R}$  is a finitely generated  $R$ -module by Theorem 4.6. It will suffice, by item (iii), to show that  $R$  has only finitely many ideals up to isomorphism. We first observe that every submodule of  $\overline{R}/R$  is cyclic. Indeed, if  $H$  is an  $R$ -submodule of  $\overline{R}$  and  $H \supseteq R$ , then  $H$  is isomorphic to an ideal of  $R$ , whence is generated by two elements, one of which can be chosen to be  $1_R$ . Since  $\overline{R}/R$  in particular is cyclic, it follows that  $\overline{R}/R \cong \overline{R}/(R :_R \overline{R}) = R/c$ . Thus every submodule of  $R/c$  is cyclic; but then  $R/c$  is an Artinian principal ideal ring and hence  $R/c$  has only finitely many ideals. Since  $\overline{R}/R \cong R/c$ , we see that there are only finitely many  $R$ -modules between  $R$  and  $\overline{R}$ .

Given a faithful ideal  $I$  of  $R$ , put  $E = (I :_R I)$ , the endomorphism ring of  $I$ . Then  $I$  is a projective  $E$ -module by Remark 4.5. Since  $E$  is semilocal,  $I$  is isomorphic to  $E$  as an  $E$ -module and therefore as an  $R$ -module. In particular,  $R$  has only finitely many faithful ideals up to  $R$ -isomorphism.

Suppose now that  $J$  is a non-zero unfaithful ideal; then  $R$  is not a domain. Notice that if  $R$  had more than two minimal primes  $\mathfrak{p}_i$ , the direct product of the  $R/\mathfrak{p}_i$  would be an  $R$ -submodule of  $\overline{R}$  requiring more than two generators. Therefore  $R$  has exactly two minimal prime ideals  $\mathfrak{p}$  and  $\mathfrak{q}$ . Exercise 4.34 implies that  $J$  is a faithful ideal of either  $R/\mathfrak{p}$  or  $R/\mathfrak{q}$ . Now  $R/\mathfrak{p}$  and  $R/\mathfrak{q}$  are discrete valuation rings: if, say,  $R/\mathfrak{p}$  were properly contained in  $\overline{R}/\mathfrak{p}$ , then  $\overline{R}/\mathfrak{p} \times R/\mathfrak{q}$  would need at least three generators as an  $R$ -module. Therefore there are, up to isomorphism, only two possibilities for  $J$ .  $\square$

## §6 Ranks of indecomposable MCM modules

Suppose  $(R, \mathfrak{m}, k)$  is a reduced local ring of dimension one, and let  $\mathfrak{p}_1, \dots, \mathfrak{p}_s$  be the minimal prime ideals of  $R$ . Let us define the *rank* of a finitely generated  $R$ -module  $M$  to be the  $s$ -tuple  $\text{rank}_R(M) = (r_1, \dots, r_s)$ , where  $r_i$  is the dimension of  $M_{\mathfrak{p}_i}$  as a vector space over the field  $R_{\mathfrak{p}_i}$ . If  $R$  has finite CM type, it follows from (DR1) and Theorem A.30 that  $s \leq e(R) \leq 3$ . There are universal bounds on the ranks of the indecomposable MCM  $R$ -modules, as  $R$  varies over one-dimensional reduced local rings with finite CM type. The precise ranks that occur have recently been worked out by N. Baeth and M. Luckas.

**4.19 Theorem** ([BL10]). *Let  $(R, \mathfrak{m})$  be a one-dimensional, analytically unramified local ring with finite CM type. Let  $s \leq 3$  be the number of minimal prime ideals of  $R$ .*

- (i) *If  $R$  is a domain, then every indecomposable finitely generated torsion-free  $R$ -module has rank 1, 2, or 3.*
- (ii) *If  $s = 2$ , then the rank of every indecomposable finitely generated torsion-free  $R$ -module is  $(0, 1)$ ,  $(1, 0)$ ,  $(1, 1)$ ,  $(1, 2)$ ,  $(2, 1)$ , or  $(2, 2)$ .*
- (iii) *If  $s = 3$ , then one can choose a fixed ordering of the minimal prime ideals so that the rank of every indecomposable finitely generated torsion-free  $R$ -module is  $(0, 0, 1)$ ,  $(0, 1, 0)$ ,  $(1, 0, 0)$ ,  $(0, 1, 1)$ ,  $(1, 0, 1)$ ,  $(1, 1, 0)$ ,  $(1, 1, 1)$ , or  $(2, 1, 1)$ .*

Moreover, there are examples showing that each of the possibilities listed actually occurs. □

The lack of symmetry in the last possibility is significant: One cannot have, for example, both an indecomposable of rank  $(2, 1, 1)$  and one of rank  $(1, 2, 1)$ . An interesting consequence of the theorem is a universal bound on modules of constant rank, even in the non-local case. First we note the following local-global theorem:

**4.20 Theorem** ([WW94]). *Let  $R$  be a one-dimensional reduced ring with finitely generated integral closure, let  $M$  be a finitely generated torsion-free  $R$ -module, and let  $r$  be a positive integer. If, for each maximal ideal  $\mathfrak{m}$  of  $R$ , the  $R_{\mathfrak{m}}$ -module  $M_{\mathfrak{m}}$  has a direct summand of constant rank  $r$ , then  $M$  has a direct summand of constant rank  $r$ .*

**4.21 Corollary** ([BL10]). *Let  $R$  be a one-dimensional reduced ring with finitely generated integral closure. Assume that  $R_{\mathfrak{m}}$  has finite Cohen-Macaulay type for each maximal ideal  $\mathfrak{m}$  of  $R$ . Then every indecomposable finitely generated torsion-free  $R$ -module of constant rank has rank 1, 2, 3, 4, 5 or 6.*

Theorem 4.19 and Corollary 4.21 correct an error in a 1994 paper of R. and S. Wiegand [WW94] where it was claimed that the sharp universal bounds were 4 in the local case and 12 in general.

If one allows non-constant ranks, there is no universal bound, even if one assumes that all localizations have multiplicity two (see [Wie88]). An interesting phenomenon is that in order to achieve rank  $(r_1, \dots, r_s)$  with *all* of the  $r_i$  large, one must have the ranks sufficiently spread out. For example [BL10, Theorem 5.5], if  $R$  has finite CM type locally and  $n \geq 8$ , every finitely generated torsion-free  $R$  module whose local ranks are between  $n$  and  $2n - 8$  has a direct summand of constant rank 6.

## §7 Exercises

**4.22 Exercise.** Let  $R = \mathbb{C}[x, y]_{(x, y)} / (y^2 - x^3 - x^2)$ . Prove that the integral closure  $\bar{R}$  is  $R \left[ \frac{y}{x} \right]$  and that  $\bar{R}$  has two maximal ideals. Prove that the completion  $\hat{R} = \mathbb{C}[[x, y]] / (y^2 - x^2 - x^3)$  has two minimal prime ideals. Show that the conductor square for  $R$  is

$$\begin{array}{ccc} R & \hookrightarrow & k[t]_U \\ \downarrow & & \downarrow \pi \\ k & \xrightarrow{\Delta} & k \times k \end{array}$$

where  $\Delta$  is the diagonal embedding,  $U$  is a certain multiplicatively closed set, and the right-hand vertical map sends  $t$  to  $(1, -1)$ .

**4.23 Exercise.** Let  $R$  be a one-dimensional CM local ring with integral closure  $\bar{R}$ , and let  $M$  be a torsion-free  $R$ -module. Show that  $\bar{R} \otimes_R M$  is torsion-free over  $\bar{R}$  if and only if  $M$  is free.

**4.24 Exercise.** Let  $c_1, \dots, c_n$  be distinct real numbers, and let  $S$  be the subring of  $\mathbb{R}[t]$  consisting of real polynomial functions  $f$  satisfying

$$f(c_1) = \dots = f(c_n) \quad \text{and} \quad f^{(k)}(c_i) = 0$$

for all  $i = 1, \dots, n$  and all  $k = 1, \dots, 3$ , where  $f^{(k)}$  denotes the  $k^{\text{th}}$  derivative. Let  $S'$  be the semilocalization of  $S$  at the union of prime ideals  $(t - c_1) \cup \dots \cup (t - c_n)$ . Let  $\mathfrak{m} = \{f \in S \mid f(c_1) = 0\}$ , and set  $R = S_{\mathfrak{m}}$ . Show that  $\mathfrak{m}$  is a maximal ideal of  $S$  and that

$$\begin{array}{ccc} R & \longrightarrow & S' \\ \downarrow & & \downarrow \pi \\ k & \longrightarrow & k[t_1]/(t_1^4) \times \dots \times k[t_n]/(t_n^4) \end{array}$$

is the conductor square for  $R$ .

**4.25 Exercise.** Let  $\Lambda$  be a ring (not necessarily commutative), and let  $M_1$  and  $M_2$  be Noetherian left  $\Lambda$ -modules. Suppose there exist surjective  $\Lambda$ -homomorphisms  $M_1 \twoheadrightarrow M_2$  and  $M_2 \twoheadrightarrow M_1$ . Prove that  $M_1 \cong M_2$ . (Cf. Exercise 1.27.)

**4.26 Exercise.** Prove the “only if” direction of (iii) in Proposition 4.7. (Hint: Use the fact that any indecomposable  $R_{\text{art}}$ -module is weakly extended from  $R$ , and use KRS (Theorem 3.4). See Proposition 10.4 if you get stuck.)

**4.27 Exercise** ([Wie94, Lemma 4]). Let  $(R, \mathfrak{m}, k)$  be a one-dimensional reduced local ring satisfying (DR1) and (DR2). Assume that  $\overline{R}$  has a maximal ideal  $\mathfrak{n}$  such that  $\ell = \overline{R}/\mathfrak{n}$  has degree 3 over  $k$ . Further, assume that  $R$  is not seminormal (equivalently,  $\overline{R}/\mathfrak{c}$  is not reduced). Prove the following:

- (i)  $\overline{R}$  is local and  $\mathfrak{m}\overline{R} = \mathfrak{n}$ .
- (ii) There is exactly one ring strictly between  $R$  and  $\overline{R}$ , namely  $S = R + \mathfrak{n}$ .
- (iii)  $R$  is Gorenstein.
- (iv)  $S$  is seminormal.

**4.28 Exercise.** Let  $(R, \mathfrak{m})$  be a one-dimensional CM local ring which is not a discrete valuation ring. Let  $\overline{R}$  be the integral closure of  $R$  in its total quotient ring  $K$ . Identify  $E = \{c \in K \mid c\mathfrak{m} \subseteq \mathfrak{m}\}$  with  $\text{End}_R(\mathfrak{m})$  via the isomorphism taking  $c$  to multiplication by  $c$ . Prove that  $E \subseteq \overline{R}$  and that  $E$  contains  $R$  properly.

**4.29 Exercise.** Let  $(R, \mathfrak{m}, k)$  be a one-dimensional reduced local ring for which  $\overline{R}$  is generated by two elements as an  $R$ -module. Prove that  $R$  satisfies the second Drozd-Rořter condition (DR2). (Hint: Pass to  $R/\mathfrak{c}$  and count lengths carefully.)

**4.30 Exercise.** Let  $R$  be a commutative ring with total quotient ring  $K = \{\text{non-zero-divisors}\}^{-1}R$ .

- (i) Let  $M$  be an  $R$ -submodule of  $K$ . Assume that  $M$  contains a non-zero-divisor of  $R$ . Prove that  $\text{Hom}_R(M, M)$  is naturally identified with  $\{\alpha \in K \mid \alpha M \subseteq M\}$ , so that every endomorphism of  $M$  is given by multiplication by an element of  $K$ .
- (ii) ([Wie94, Lemma 1]) Suppose  $A$  and  $B$  are subrings of  $K$  with  $R \subseteq A \cap B$ . Prove that if  $A$  and  $B$  are isomorphic as  $R$ -modules then  $A = B$ .

**4.31 Exercise.** Let  $R$  be a reduced one-dimensional local ring. Suppose  $R$  has an infinite family of ideals that are pairwise non-isomorphic as  $R$ -modules. Prove that  $R$  has infinite CM type. (Hint: the *Goldie dimension* of  $R$  is the least integer  $s$  such that every ideal of  $R$  is a direct sum of at most  $s$  indecomposable ideals. Prove that  $s < \infty$ .)

**4.32 Exercise.** Prove Theorem 4.16.

**4.33 Exercise** ([Bas63, Theorem 6.4]). Let  $(R, \mathfrak{m})$  be a one-dimensional CM ring, and suppose  $\mathfrak{m}$  can be generated by two elements. Prove that  $R$  is Gorenstein.

**4.34 Exercise.** Let  $(R, \mathfrak{m})$  be a reduced one-dimensional local ring, and let  $M$  be a MCM  $R$ -module. Prove that  $(0 :_R M)$  is the intersection of the minimal prime ideals  $\mathfrak{p}$  for which  $M_{\mathfrak{p}} \neq 0$ .

## *Invariant theory*

In this chapter we describe an abundant source of MCM modules coming from invariant theory. We consider finite subgroups  $G \subseteq \mathrm{GL}(n, k)$ , with order invertible in the field  $k$ , acting by linear changes of variable on the power series ring  $S = k[[x_1, \dots, x_n]]$ . The invariant subring  $R = S^G$  is a complete local CM normal domain of dimension  $n$ , and comes equipped with a natural MCM module, namely the ring  $S$  considered as an  $R$ -module. The main goal of this chapter is a collection of one-one correspondences between:

- (i) the indecomposable  $R$ -direct summands of  $S$ ;
- (ii) the indecomposable projective modules over the endomorphism ring  $\mathrm{End}_R(S)$ ;
- (iii) the indecomposable projective modules over the twisted group ring  $S\#G$ ; and
- (iv) the irreducible  $k$ -representations of  $G$ .

We also introduce two directed graphs (quivers), the McKay quiver and the Gabriel quiver, associated with these data, and show that they are isomorphic.

In the next chapter we will specialize to the case  $n = 2$ , and show that in fact every indecomposable MCM  $R$ -module is a direct summand of  $S$ , so that the correspondences above classify all the MCM  $R$ -modules.

## §1 The skew group ring

We begin with a little general invariant theory of arbitrary commutative rings, focusing on a central object: the skew group ring.

**5.1 Notation.** Fix the following notation for this section. Let  $S$  be an arbitrary commutative ring and  $G \subseteq \text{Aut}(S)$  a finite group of automorphisms of  $S$ . We always assume that  $|G|$  is a unit in  $S$ . Let  $R = S^G$  be the ring of invariants, so  $s \in R$  if and only if  $\sigma(s) = s$  for every  $\sigma \in G$ .

**5.2 Example.** Two central examples are given by linear actions on polynomial and power series rings. Let  $k$  be a field and  $V$  a  $k$ -vector space of dimension  $n$ , with basis  $x_1, \dots, x_n$ . Let  $G$  be a finite subgroup of  $\text{GL}(V) \cong \text{GL}(n, k)$ , acting naturally by linear changes of coordinates on  $V$ . We extend this action to monomials  $x_1^{a_1} \cdots x_n^{a_n}$  multiplicatively, and then to all polynomials in  $x_1, \dots, x_n$  by linearity. This defines an action of  $G$  on the polynomial ring  $k[x_1, \dots, x_n]$ . Extending the action of  $G$  to infinite sums in the obvious way, we obtain also an action on the power series ring  $k[[x_1, \dots, x_n]]$ . In either case we say that  $G$  acts on  $S$  via linear changes of variables.

It is an old result of Cartan [Car57] that when  $S$  is either the polynomial or the power series ring, we may assume that the action of an arbitrary subgroup  $G \subseteq \text{Aut}_k(S)$  is in fact linear. This is the first instance where the assumption that  $|G|$  be invertible in  $S$  will be used; it will be essential throughout.

**5.3 Lemma.** *Let  $k$  be a field and let  $S$  be either the polynomial ring  $k[x_1, \dots, x_n]$  or the power series ring  $k[[x_1, \dots, x_n]]$ . Let  $G \subseteq \text{Aut}_k(S)$  a finite group of  $k$ -*

algebra automorphisms of  $S$  with  $|G|$  invertible in  $k$ . Then there exists a finite group  $G' \subseteq \mathrm{GL}(n, k)$ , acting on  $S$  via linear changes of variables such that  $S^{G'} \cong S^G$ .

*Proof.* Let  $V = (x_1, \dots, x_n)/(x_1, \dots, x_n)^2$  be the vector space of linear forms of  $S$ . Then  $G$  acts on  $V$ , giving a group homomorphism  $\varphi: G \rightarrow \mathrm{GL}(V)$ . Set  $G' = \varphi(G)$ , and extend the action of  $G'$  linearly to all of  $S$  by linear changes of variables as in Example 5.2.

Define a ring homomorphism  $\theta: S \rightarrow S$  by the rule

$$\theta(s) = \frac{1}{|G|} \sum_{\sigma \in G} \varphi(\sigma)^{-1} \sigma(s).$$

Since  $\theta$  restricts to the identity on  $V$ , it is an automorphism of  $S$ . For an element  $\tau \in G$ , we have  $\varphi(\tau) \circ \theta = \theta \circ \tau$  as automorphisms of  $S$ . Hence the actions of  $G$  and  $G'$  are conjugate, and it follows that  $S^{G'} \cong S^G$ .  $\square$

Let  $S$ ,  $G$ , and  $R$  be as in 5.1. The fact that  $|G|$  is invertible allows us to define the *Reynolds operator*  $\rho: S \rightarrow R$  by sending  $s \in S$  to the average of its orbit:

$$\rho(s) = \frac{1}{|G|} \sum_{\sigma \in G} \sigma(s).$$

Then  $\rho$  is  $R$ -linear, and it splits the inclusion  $R \subseteq S$ , thereby making  $R$  an  $R$ -direct summand of  $S$ . It follows (Exercise 5.27) that  $IS \cap R = I$  for every ideal  $I$  of  $R$ , whence  $R$  is Noetherian, resp. local, resp. complete, if  $S$  is.

The extension  $R \rightarrow S$  is integral. Indeed, every element  $s \in S$  is a root of the monic polynomial  $\prod_{\sigma \in G} (x - \sigma(s))$ , whose coefficients are elementary symmetric polynomials in the conjugates  $\{\sigma(s)\}$ , so are in  $R$ . In particular it follows that  $R$  and  $S$  have the same Krull dimension.

Suppose that  $S$  is a domain with quotient field  $K$ , and let  $F$  be the quotient field of  $R$ . Then  $G$  acts naturally on  $K$ , and by Exercise 5.28 the fixed field is  $F$ , so that  $K/F$  is a Galois extension with Galois group  $G$ .

If  $S$  is a domain and is also Noetherian, then  $S$  is a finitely generated  $R$ -module. Since this fact seems not to be well-known in this generality, we give a proof here. We learned this argument from [BD08]. For the classical result that finite generation holds if  $S$  is a finitely generated algebra over a field, see Exercise 5.29.

**5.4 Proposition.** *Let  $S$  be a Noetherian integral domain and let  $G \subseteq \text{Aut}(S)$  be a finite group with  $|G|$  invertible in  $S$ . Set  $R = S^G$ . Then  $S$  is a finitely generated  $R$ -module of rank equal to  $|G|$ .*

*Proof.* Let  $F$  and  $K$  be the quotient fields of  $R$  and  $S$ , respectively. The Reynolds operator  $\rho: S \rightarrow R$  extends to an operator  $\rho: K \rightarrow F$  defined by the same rule. (In fact  $\rho$  is nothing but a constant multiple of the usual trace form  $K$  to  $F$ .)

Fix a basis  $\alpha_1, \dots, \alpha_n$  for  $K$  over  $F$ . We may assume that  $\alpha_i \in S$  for each  $i$ . Indeed, if  $s/t \in K$  with  $s$  and  $t$  in  $S$ , we may multiply numerator and denominator by product of the distinct images of  $t$  under  $G$  to assume  $t \in R$ , then replace  $s/t$  by  $s$  without affecting the  $F$ -span.

By [Lan02, Corollary VI.5.3], there is a dual basis  $\alpha'_1, \dots, \alpha'_n$  such that  $\rho(\alpha_i \alpha'_j) = \delta_{ij}$ . Let  $M$  denote the  $R$ -module span of  $\{\alpha'_1, \dots, \alpha'_n\}$  in  $K$ . We claim that  $S \subseteq M$ , so that  $S$  is a submodule of a finitely generated  $R$ -module, hence is finitely generated.

Let  $s \in S$ , and write  $s = \sum_i f_i \alpha'_i$  with  $f_1, \dots, f_n \in F$ . It suffices to prove that  $f_j \in R$  for each  $j$ . Note that since  $\alpha_j \in S$  for each  $j$ , we have  $\rho(s \alpha_j) \in R$

for  $j = 1, \dots, n$ . But

$$\rho(s\alpha_j) = \sum_i f_i \alpha_i \alpha'_j = f_j$$

so that  $S \subseteq M$ , as claimed. The statement about the rank of  $S$  over  $R$  is immediate.  $\square$

If in addition  $S$  is a normal domain then the same is true of  $R$ . Indeed, any element  $\alpha \in F$  which is integral over  $R$  is also integral over  $S$ . Since  $S$  is integrally closed in  $K$ , we have  $\alpha \in S \cap F = R$ .

Finally, if  $S$  and  $R$  are local rings, then we have by Exercise 5.30 that  $\text{depth} R \geq \text{depth} S$ . In particular  $R$  is CM if  $S$  is, and in this case  $S$  is a MCM  $R$ -module. (This statement, for example, is quite false if  $|G|$  is divisible by  $\text{char}(k)$  [Fog81].)

We now introduce the skew group ring.

**5.5 Definition.** Let  $S$  be a ring and  $G \subseteq \text{Aut}(S)$  a finite group of automorphisms with order invertible in  $S$ . Let  $S\#G$  denote the *skew group ring* of  $S$  and  $G$ . As an  $S$ -module,  $S\#G = \bigoplus_{\sigma \in G} S \cdot \sigma$  is free on the elements of  $G$ ; the product of two elements  $s \cdot \sigma$  and  $t \cdot \tau$  is

$$(s \cdot \sigma)(t \cdot \tau) = s\sigma(t) \cdot \sigma\tau.$$

Thus moving  $\sigma$  past  $t$  “twists” the ring element.

**5.6 Remarks.** In the notation of Definition 5.5, a left  $S\#G$ -module  $M$  is nothing but an  $S$ -module with a compatible action of  $G$ , in the sense that  $\sigma(sm) = \sigma(s)\sigma(m)$  for all  $\sigma \in G$ ,  $s \in S$ ,  $m \in M$ . We have  $\sigma(st) = \sigma(s)\sigma(t)$  for all  $s$  and  $t$  in  $S$ , and so  $S$  itself is a left  $S\#G$ -module. Of course  $S\#G$  is also a left module over itself.

Similarly, an  $S\#G$ -linear map between left  $S\#G$ -modules is an  $S$ -module homomorphism  $f: M \rightarrow N$  respecting the action of  $G$ , so that  $f(\sigma(m)) = \sigma(f(m))$ . This allows us to define a left  $S\#G$ -module structure on  $\text{Hom}_S(M, N)$ , when  $M$  and  $N$  are  $S\#G$ -modules, by  $\sigma(f)(m) = \sigma(f(\sigma^{-1}(m)))$ . It follows that an  $S$ -linear map  $f: M \rightarrow N$  between  $S\#G$ -modules is  $S\#G$ -linear if and only if it is invariant under the  $G$ -action. Indeed, if  $\sigma(f) = f$  for all  $\sigma \in G$ , then  $f(m) = \sigma(f(\sigma^{-1}(m)))$ , so that  $\sigma^{-1}(f(m)) = f(\sigma^{-1}(m))$  for all  $\sigma \in G$ . Concisely,

$$(5.6.1) \quad \text{Hom}_{S\#G}(M, N) = \text{Hom}_S(M, N)^G.$$

Since the order of  $G$  is invertible in  $S$ , taking  $G$ -invariants of an  $S\#G$ -modules is an exact functor (Exercise 5.32). In particular,  $-^G$  commutes with taking cohomology, so (5.6.1) extends to higher Exts:

$$(5.6.2) \quad \text{Ext}_{S\#G}^i(M, N) = \text{Ext}_S^i(M, N)^G$$

for all  $S\#G$ -modules  $M$  and  $N$  and all  $i \geq 0$ . This has the following wonderful consequence, the easy proof of which we leave as an exercise.

**5.7 Proposition.** *An  $S\#G$ -module  $M$  is projective if and only if it is projective as an  $S$ -module.*

**5.8 Corollary.** *If  $S$  is a polynomial or power series ring in  $n$  variables, then the skew group ring  $S\#G$  has global dimension equal to  $n$ .*

We leave the proof of the corollary to the reader; the next example will no doubt be useful.

**5.9 Example.** Set  $S$  be either the polynomial ring  $k[x_1, \dots, x_n]$  or the power series ring  $k[[x_1, \dots, x_n]]$ , with  $G \subseteq \mathrm{GL}(n, k)$  acting by linear changes of variables as in Example 5.2. The Koszul complex  $K_\bullet$  on the variables  $\mathbf{x} = x_1, \dots, x_n$  is a minimal  $S\#G$ -linear resolution of the residue field  $k$  of  $S$  (with trivial action of  $G$ ). In detail, let  $V = (x_1, \dots, x_n)/(x_1, \dots, x_n)^2$  be the  $k$ -vector space with basis  $x_1, \dots, x_n$ , and

$$K_p = K_p(\mathbf{x}, S) = S \otimes_k \bigwedge^p V$$

for  $p \geq 0$ . The differential  $\partial_p: K_p \rightarrow K_{p-1}$  is given by

$$\partial_p(x_{i_1} \wedge \cdots \wedge x_{i_p}) = \sum_{j=1}^p (-1)^{j+1} x_{i_j} (x_{i_1} \wedge \cdots \wedge \widehat{x_{i_j}} \wedge \cdots \wedge x_{i_p}),$$

where  $\{x_{i_1} \wedge \cdots \wedge x_{i_p}\}$ ,  $1 \leq i_1 < i_2 < \cdots < i_p \leq n$ , are the natural basis vectors for  $\bigwedge^p V$ . Since the  $x_i$  form an  $S$ -regular sequence,  $K_\bullet$  is acyclic, minimally resolving  $k$ .

The exterior powers  $\bigwedge^p V$  carry a natural action of  $G$ , by  $\sigma(x_{i_1} \wedge \cdots \wedge x_{i_p}) = \sigma(x_{i_1}) \wedge \cdots \wedge \sigma(x_{i_p})$ , and it's easy to see that the differentials  $\partial_p$  are  $S\#G$ -linear for this action. Since the modules appearing in  $K_\bullet$  are free  $S$ -modules, they are projective over  $S\#G$ , so we see that  $K_\bullet$  resolves the trivial module  $k$  over  $S\#G$ . Since every projective over  $S\#G$  is free over  $S$ , the Depth Lemma then shows that  $\mathrm{pd}_{S\#G} k$  cannot be any smaller than  $n$ .

**5.10 Remark.** Let  $S$  and  $G$  be as in 5.1. The ring  $S$  sits inside  $S\#G$  naturally via  $S = S \cdot 1_G$ . However, it also sits in a more symmetric fashion via a modified version of the Reynolds operator. Define  $\widehat{\rho}: S \rightarrow S\#G$  by

$$\widehat{\rho}(s) = \frac{1}{|G|} \sum_{\sigma \in G} \sigma(s) \cdot \sigma.$$

One checks easily that  $\hat{\rho}$  is an injective ring homomorphism, and that the image of  $\hat{\rho}$  is precisely equal to  $(S\#G)^G$ , the fixed points of  $S\#G$  under the left action of  $G$ . In particular,  $\hat{\rho}(1)$  is an idempotent of  $S\#G$ .

## §2 The endomorphism algebra

The “twisted” multiplication on the skew group ring  $S\#G$  is cooked up precisely so that the homomorphism

$$\gamma: S\#G \longrightarrow \text{End}_R(S), \quad \gamma(s \cdot \sigma)(t) = s\sigma(t),$$

is a ring homomorphism extending the group homomorphism  $G \longrightarrow \text{End}_R(S)$  that defines the action of  $G$  on  $S$ . In words,  $\gamma$  simply considers an element of  $S\#G$  as an endomorphism of  $S$ .

In general,  $\gamma$  is neither injective nor surjective, even when  $S$  is a polynomial or power series ring. Under an additional assumption on the extension  $R \longrightarrow S$ , however, it is both, by a theorem of Auslander [Aus62]. We turn now to this additional assumption, explaining which will necessitate a brief detour through ramification theory. See Appendix B for the details.

Recall (Definition B.1) that a local homomorphism of local rings  $(A, \mathfrak{m}, k) \longrightarrow (B, \mathfrak{n}, \ell)$  which is essentially of finite type is called *unramified* provided  $\mathfrak{m}B = \mathfrak{n}$  and the induced homomorphism  $A/\mathfrak{m} \longrightarrow B/\mathfrak{m}B$  is a finite separable field extension. Equivalently (Proposition B.9), the exact sequence

$$(5.10.1) \quad 0 \longrightarrow \mathcal{J} \longrightarrow B \otimes_A B \xrightarrow{\mu} B \longrightarrow 0,$$

where  $\mu: B \otimes_A B \longrightarrow B$  is the *diagonal map* defined by  $\mu(b \otimes b') = bb'$  and  $\mathcal{J}$  is the ideal of  $B \otimes_A B$  generated by all elements of the form  $b \otimes 1 - 1 \otimes b$ ,

splits as  $B \otimes_A B$ -modules. We say that a ring homomorphism  $A \rightarrow B$  which is essentially of finite type is *unramified in codimension one* if the induced local homomorphism  $A_{\mathfrak{q} \cap A} \rightarrow B_{\mathfrak{q}}$  is unramified for every prime ideal  $\mathfrak{q}$  of height one in  $B$ . If  $A \rightarrow B$  is module-finite, then it is equivalent to quantify over height-one primes in  $A$ .

In order to leverage codimension-one information into a global conclusion, we will use a general lemma about normal domains due to Auslander and Buchsbaum [AB59], which will reappear repeatedly in other contexts.

**5.11 Lemma.** *Let  $A$  be a normal domain and let  $f : M \rightarrow N$  be a homomorphism of finitely generated  $A$ -modules such that  $M$  satisfies the condition  $(S_2)$  and  $N$  satisfies  $(S_1)$ . If  $f_{\mathfrak{p}}$  is an isomorphism for every prime ideal  $\mathfrak{p}$  of codimension 1 in  $A$ , then  $f$  is an isomorphism.*

*Proof.* Set  $K = \ker f$  and  $C = \operatorname{cok} f$ , so that we have the exact sequence

$$(5.11.1) \quad 0 \longrightarrow K \longrightarrow M \xrightarrow{f} N \longrightarrow C \longrightarrow 0.$$

Since  $f_{(0)}$  is an isomorphism,  $K_{(0)} = 0$ , which means that  $K$  is annihilated by a non-zero element of  $A$ . But  $M$  is torsion-free, so  $K = 0$ . As for  $C$ , suppose that  $C \neq 0$  and choose  $\mathfrak{p} \in \operatorname{Ass} C$ . Then  $\mathfrak{p}$  has height at least 2. Localize (5.11.1) at  $\mathfrak{p}$ :

$$0 \longrightarrow M_{\mathfrak{p}} \longrightarrow N_{\mathfrak{p}} \longrightarrow C_{\mathfrak{p}} \longrightarrow 0.$$

As  $M$  is reflexive, it satisfies  $(S_2)$ , so  $M_{\mathfrak{p}}$  has depth at least 2. On the other end, however,  $C_{\mathfrak{p}}$  has depth 0, which contradicts the Depth Lemma.  $\square$

**5.12 Theorem** (Auslander [Aus62, Prop. 3.4]). *Let  $(S, \mathfrak{n})$  be a Noetherian normal domain and let  $G$  be a finite subgroup of  $\text{Aut}(S)$  with order invertible in  $S$ . Set  $R = S^G$ . If  $R \rightarrow S$  is unramified in codimension one, then the ring homomorphism  $\gamma: S\#G \rightarrow \text{End}_R(S)$  defined by  $\gamma(s \cdot \sigma)(t) = s\sigma(t)$  is an isomorphism.*

*Proof.* Since  $S\#G$  is isomorphic to a direct sum of copies of  $S$  as an  $S$ -module, it satisfies  $(S_2)$  over  $R$ . The endomorphism ring  $\text{End}_R(S)$  has depth at least  $\min\{2, \text{depth } S\}$  over each localization of  $R$  by Exercise 5.37, so satisfies  $(S_1)$ . Thus by Lemma 5.11 it suffices to prove that  $\gamma$  is an isomorphism in height one. At height one primes, the extension is unramified, so we may assume for the proof that  $R \rightarrow S$  is unramified.

The strategy of the proof is to define a right splitting  $\text{End}_R(S) \rightarrow S\#G$  for  $\gamma: S\#G \rightarrow \text{End}_R(S)$  based on the diagram below.

$$(5.12.1) \quad \begin{array}{ccc} S\#G & \xrightarrow{\gamma} & \text{End}_R(S) \\ \tilde{\mu} \uparrow & & \downarrow f \mapsto f \otimes \hat{\rho} \\ S \otimes_R (S\#G) & \xleftarrow{\text{ev}_e} & \text{Hom}_S(S \otimes_R S, S \otimes_R (S\#G)) \end{array}$$

We now define each of the arrows in (5.12.1) in turn. Recall from Remark 5.10 that the homomorphism

$$\hat{\rho}: S \rightarrow S\#G, \quad \hat{\rho}(s) = \frac{1}{|G|} \sum_{\sigma \in G} \sigma(s) \cdot \sigma$$

embeds  $S$  as the fixed points  $(S\#G)^G$  of  $S\#G$ . Thus  $- \otimes \hat{\rho}$  defines the right-hand vertical arrow in (5.12.1).

Since we assume  $R \rightarrow S$  is unramified, the short exact sequence

$$(5.12.2) \quad 0 \longrightarrow \mathcal{J} \longrightarrow S \otimes_R S \xrightarrow{\mu} S \longrightarrow 0$$

splits as  $S \otimes_R S$ -modules, where as before  $\mu: S \otimes_R S \rightarrow S$  is the diagonal map and  $\mathcal{J}$  is generated by all elements of the form  $s \otimes 1 - 1 \otimes s$  for  $s \in S$ . Tensoring (5.12.2) on the right with  $S\#G$  thus gives another split exact sequence

$$(5.12.3) \quad 0 \longrightarrow \mathcal{J} \otimes_S (S\#G) \longrightarrow S \otimes_R (S\#G) \xrightarrow{\tilde{\mu}} S\#G \longrightarrow 0$$

with  $\tilde{\mu}(t \otimes s \cdot \sigma) = ts \cdot \sigma \in S\#G$  defining the left-hand vertical arrow in (5.12.1).

Let  $j: S \rightarrow S \otimes_R S$  be a splitting for (5.12.2), and set  $\epsilon = j(1)$ . Then  $\mu(\epsilon) = 1$  and

$$(5.12.4) \quad (1 \otimes s - s \otimes 1)\epsilon = 0$$

for all  $s \in S$ . Evaluation at  $\epsilon \in S \otimes_R S$  defines

$$\text{ev}_\epsilon: \text{Hom}_S(S \otimes_R S, S \otimes_R (S\#G)) \rightarrow S \otimes_R (S\#G),$$

the bottom row of the diagram. Now we show that for an arbitrary  $f \in \text{End}_R(S)$ , we have

$$\gamma(\tilde{\mu}(\text{ev}_\epsilon(f \otimes \hat{\rho}))) = \frac{1}{|G|} f.$$

Write  $\epsilon = \sum_i x_i \otimes y_i$  for some elements  $x_i, y_i \in S$ . We claim first that

$$\sum_i x_i \sigma(y_i) = \begin{cases} 1 & \text{if } \sigma = 1_G, \text{ and} \\ 0 & \text{otherwise.} \end{cases}$$

To see this, note that

$$(s \otimes 1) \left( \sum_i x_i \otimes y_i \right) = (1 \otimes s) \left( \sum_i x_i \otimes y_i \right)$$

for every  $s \in S$  by (5.12.4). Apply the endomorphism  $1 \otimes \sigma$  to both sides, obtaining

$$\sum_i s x_i \otimes \sigma(y_i) = \sum_i x_i \otimes \sigma(s) \sigma(y_i).$$

Collapse the tensor products with  $\mu: S \otimes_R S \rightarrow S$ , and factor each side, getting

$$s \left( \sum_i x_i \sigma(y_i) \right) = \sigma(s) \left( \sum_i x_i \sigma(y_i) \right).$$

This holds for every  $s \in S$ , so that either  $\sigma = 1_G$  or  $\sum_i x_i \sigma(y_i) = 0$ , proving the claim.

Now fix  $f \in \text{End}_R(S)$  and  $s \in S$ . Unravelling all the definitions, we find

$$\begin{aligned} \gamma[\tilde{\mu}[(f \otimes \hat{\rho})(\epsilon)]](s) &= \gamma[\tilde{\mu}[(f \otimes \hat{\rho})(\sum_i x_i \otimes y_i)]](s) \\ &= \gamma[\tilde{\mu}(\sum_i f(x_i) \otimes \hat{\rho}(y_i))](s) \\ &= \gamma[(\sum_i f(x_i) \hat{\rho}(y_i))](s) \\ &= \gamma\left[\left(\sum_i f(x_i) \left(\frac{1}{|G|} \sum_{\sigma} \sigma(y_i) \cdot \sigma\right)\right)\right](s) \\ &= \frac{1}{|G|} \sum_i f(x_i) (\sum_{\sigma} \sigma(y_i) \sigma(s)). \end{aligned}$$

Now, since the sum over  $\sigma$  is fixed by  $G$ , it lives in  $R$ , so

$$\begin{aligned} &= \frac{1}{|G|} f(\sum_i x_i (\sum_{\sigma} \sigma(y_i) \sigma(s))) \\ &= \frac{1}{|G|} f(\sum_{\sigma} (\sum_i x_i \sigma(y_i)) \sigma(s)) \\ &= \frac{1}{|G|} f(\sum_i x_i y_i s) \end{aligned}$$

by the claim. By the definition of  $\epsilon = \sum x_i \otimes y_i$ , this last expression is equal to  $\frac{1}{|G|} f(s)$ , as desired. Therefore  $\gamma: S \# G \rightarrow \text{End}_R(S)$  is a split surjection. Since both source and target of  $\gamma$  are torsion-free  $R$ -modules of rank equal to  $|G|^2$ , this forces  $\gamma$  to be an isomorphism.  $\square$

When  $S$  is a polynomial or power series ring and  $G \subseteq \mathrm{GL}(n, k)$  acts linearly, the ramification of  $R \rightarrow S$  is explained by the presence of *pseudo-reflections* in  $G$ .

**5.13 Definition.** Let  $k$  be a field. An element  $\sigma \in \mathrm{GL}(n, k)$  of finite order is called a *pseudo-reflection* provided the fixed subspace  $V^\sigma = \{v \in k^{(n)} \mid \sigma(v) = v\}$  has codimension one in  $k^{(n)}$ . Equivalently,  $\sigma - I_n$  has rank 1. We say a subgroup  $G \subseteq \mathrm{GL}(n, k)$  is *small* if it contains no pseudo-reflections.

If a pseudo-reflection  $\sigma$  is diagonalizable, then  $\sigma$  is similar to a diagonal matrix with diagonal entries  $1, \dots, 1, \lambda$  with  $\lambda \neq 1$  a root of unity. In fact, one can show (Exercise 5.38) that a pseudo-reflection with order prime to  $\mathrm{char}(k)$  is necessarily diagonalizable.

The importance of pseudo-reflections in invariant theory generally begins with the foundational theorem of Shephard-Todd (Theorem B.27), which says that, in the case  $S = k[[x_1, \dots, x_n]]$ , the invariant ring  $R = S^G$  is a regular local ring if and only if  $G$  is generated by pseudo-reflections.

More relevant for our purposes, pseudo-reflections control the “large ramification” of invariant rings. We banish the proof of this fact to the Appendix (Theorem B.29).

**5.14 Theorem.** Let  $k$  be a field and  $G \subseteq \mathrm{GL}(n, k)$  a finite group with order invertible in  $k$ . Let  $S$  be either the polynomial ring  $k[x_1, \dots, x_n]$  or the power series ring  $k[[x_1, \dots, x_n]]$ , with  $G$  acting by linear changes of variables. Set  $R = S^G$ . Then the extension  $R \rightarrow S$  is unramified in codimension one if and only if  $G$  is small.

In fact, by a theorem of Prill, we could always assume that  $G$  is small. Specifically, we may replace  $S$  and  $G$  by another power series ring  $S'$  (possibly with fewer variables) and finite group  $G'$ , respectively, so that  $G'$  is small and  $S'^{G'} \cong S^G$ . See Proposition B.30 for this, which we will not use in this chapter.

In view of Theorem 5.14, we can restate Theorem 5.12 as follows for linear actions.

**5.15 Theorem.** *Let  $k$  be a field and  $G \subseteq \mathrm{GL}(n, k)$  a finite group with order invertible in  $k$ . Let  $S$  be either the polynomial ring  $k[x_1, \dots, x_n]$  or the power series ring  $k[[x_1, \dots, x_n]]$ , with  $G$  acting by linear changes of variables. Set  $R = S^G$ . If  $G$  contains no pseudo-reflections, then the natural homomorphism  $\gamma: S\#G \rightarrow \mathrm{End}_R(S)$  is an isomorphism.*

**5.16 Corollary.** *With notation as in Theorem 5.15, assume that  $G$  contains no pseudo-reflections. Then we have ring isomorphisms*

$$S\#G \xrightarrow{u} (S\#G)^{op} \xrightarrow{v} \mathrm{End}_{S\#G}(S\#G) \xrightarrow{\mathrm{res}} \mathrm{End}_R(S)$$

where  $u(s \cdot \sigma) = \sigma^{-1}(s) \cdot \sigma^{-1}$ ,  $v(s \cdot \sigma)(t \cdot \tau) = (t \cdot \tau)(s \cdot \sigma)$ , and  $\mathrm{res}$  is restriction to the subring  $\hat{\rho}(S) = (S\#G)^G$ . The composition of these maps is the isomorphism  $\gamma$ . These isomorphisms induce one-one correspondences among

- the indecomposable direct summands of  $S$  as an  $R$ -module;
- the indecomposable direct summands of  $\mathrm{End}_R(S)$  as an  $\mathrm{End}_R(S)$ -module;
- and
- the indecomposable direct summands of  $S\#G$  as an  $S\#G$ -module.

Explicitly, if  $P_0, \dots, P_d$  are the indecomposable direct summands of  $S\#G$ , then  $P_j^G$ , for  $j = 0, \dots, d$  are the direct summands of  $S$  as an  $R$ -module. They are in particular MCM  $R$ -modules.

*Proof.* It's easy to check that  $\iota$  and  $\nu$  are isomorphisms, and that the composition  $\text{res} \circ \nu \circ \iota$  is equal to  $\gamma$ . The primitive idempotents of  $\text{End}_R(S)$  correspond both to the indecomposable  $R$ -direct summands of  $S$  and to the indecomposable  $\text{End}_R(S)$ -projectives, while those of  $\text{End}_{S\#G}(S\#G)$  correspond to the indecomposable  $S\#G$ -projective modules. The fact that  $(S\#G)^G = S$  implies the penultimate statement, and the fact that  $S$  is MCM over  $R$  was observed already.  $\square$

We have not yet shown that the indecomposable direct summands of  $S\#G$  as an  $S\#G$ -module are all the indecomposable projective  $S\#G$ -modules. This will follow from the first result of the next section, where we prove that  $S\#G$  (and hence  $\text{End}_R(S)$ ) satisfies KRS when  $S$  is complete.

### §3 Group representations and the McKay-Gabriel quiver

The module theory of the skew group ring  $S\#G$ , where  $G \subseteq \text{GL}(n, k)$  acts linearly on the power series ring  $S$ , faithfully reflects the representation theory of  $G$ . In this section we make this assertion precise.

Throughout the section, we consider linear group actions on power series rings, so that  $G \subseteq \text{GL}(n, k)$  is a finite group of order relatively prime

to the characteristic of  $k$ , acting on  $S = k[[x_1, \dots, x_n]]$  by linear changes of variables, with invariant ring  $R = S^G$ . Let  $S\#G$  be the skew group ring.

**5.17 Definition.** Let  $M$  be an  $S\#G$ -module and  $W$  a  $k$ -representation of  $G$ , that is, a module over the group algebra  $kG$ . Define an  $S\#G$ -module structure on  $M \otimes_k W$  by the diagonal action

$$s\sigma(m \otimes w) = s\sigma(m) \otimes \sigma(w).$$

Define a functor  $\mathcal{F}$  from the category of finite-dimensional  $k$ -representations  $W$  of  $G$  to that of finitely generated  $S\#G$ -modules by

$$\mathcal{F}(W) = S \otimes_k W$$

and similarly for homomorphisms. For any  $W$ ,  $\mathcal{F}(W)$  is obviously a free  $S$ -module and thus a projective  $S\#G$ -module.

In the opposite direction, let  $P$  be a finitely generated projective  $S\#G$ -module. Then  $P/\mathfrak{n}P$  is a finite-dimensional  $k$ -vector space with an action of  $G$ , that is, a  $k$ -representation of  $G$ . Define a functor  $\mathcal{G}$  from projective  $S\#G$ -modules to  $k$ -representations of  $G$  by

$$\mathcal{G}(P) = P/\mathfrak{n}P$$

and correspondingly on homomorphisms.

**5.18 Proposition.** *The functors  $\mathcal{F}$  and  $\mathcal{G}$  form an adjoint pair, that is,*

$$\mathrm{Hom}_{kG}(\mathcal{G}(P), W) = \mathrm{Hom}_{S\#G}(P, \mathcal{F}(W)),$$

*and are inverses of each other on objects. Concretely, for a projective  $S\#G$ -module  $P$  and a  $k$ -representation  $W$  of  $G$ , we have*

$$S \otimes_k P/\mathfrak{n}P \cong P$$

and

$$(S \otimes_k W)/\mathfrak{n}(S \otimes_k W) \cong W.$$

In particular, there is a one-one correspondence between the isomorphism classes of indecomposable projective  $S\#G$ -modules and the irreducible  $k$ -representations of  $G$ .

*Proof.* It is clear that  $\mathcal{G}(\mathcal{F}(W)) \cong W$ , since

$$(S \otimes_k W)/\mathfrak{n}(S \otimes_k W) \cong S/\mathfrak{n} \otimes_k W \cong W.$$

To show that the other composition is also the identity, let  $P$  be a projective  $S\#G$ -module. Then  $\mathcal{F}(\mathcal{G}(P)) = S \otimes_k P/\mathfrak{n}P$  is a projective  $S\#G$ -module, with a natural projection onto  $P/\mathfrak{n}P$ . Of course, the original projective  $P$  also maps onto  $P/\mathfrak{n}P$ . This latter is in fact a projective cover of  $P/\mathfrak{n}P$  (since idempotents in  $kG$  lift to  $S\#G$  via the retraction  $kG \rightarrow S\#G \rightarrow kG$ ). There is thus a lifting  $S \otimes_k P/\mathfrak{n}P \rightarrow P$ , which is surjective modulo  $\mathfrak{n}P$ . Nakayama's Lemma then implies that the lifting is surjective, so split, as  $P$  is projective. Comparing ranks over  $S$ , we must have  $S \otimes_k P/\mathfrak{n}P \cong P$ .  $\square$

**5.19 Corollary.** *Let  $V_0, \dots, V_d$  be a complete set of non-isomorphic simple  $kG$ -modules. Then*

$$S \otimes_k V_0, \dots, S \otimes_k V_d$$

*is a complete set of non-isomorphic indecomposable finitely generated projective  $S\#G$ -modules. Furthermore, the category of finitely generated projective  $S\#G$ -modules satisfies the KRS property, i.e. each finitely generated projective  $P$  is isomorphic to a unique direct sum  $\bigoplus_{i=0}^d (S \otimes_k V_i)^{n_i}$ .*

Putting together the one-one correspondences obtained so far, we have

**5.20 Corollary.** *Let  $k$  be a field,  $S = k[[x_1, \dots, x_n]]$ , and  $G \subseteq \mathrm{GL}(n, k)$  a finite group acting linearly on  $S$  without pseudo-reflections and such that  $|G|$  is invertible in  $k$ . Then there are one-one correspondences between*

- *the indecomposable direct summands of  $S$  as an  $R$ -module;*
- *the indecomposable finitely generated projective  $\mathrm{End}_R(S)$ -modules;*
- *the indecomposable finitely generated projective  $S\#G$ -modules; and*
- *the irreducible  $kG$ -modules.*

*The correspondence between the first and last items is induced by the equivalence of categories between  $k$ -representations of  $G$  and  $\mathrm{add}_R(S)$  defined by  $W \mapsto (S \otimes_k W)^G$ .*

*Explicitly, if  $V_0, \dots, V_d$  are the non-isomorphic irreducible representations of  $G$  over  $k$ , then the modules of covariants*

$$M_j = (S \otimes_k V_j)^G, \quad j = 0, \dots, d$$

*are the indecomposable  $R$ -direct summands of  $S$ . They are in particular MCM  $R$ -modules. Furthermore, we have  $\mathrm{rank}_R M_j = \dim_k V_j$ .*

The one-one correspondence between projectives, representations, and certain MCM modules obtained so far extends to an isomorphism of two graphs naturally associated to these data, as we now explain. We will meet a third incarnation of these graphs in Chapter 12.

We keep all the notation established so far in this section, and additionally let  $V_0, \dots, V_d$  be a complete set of the non-isomorphic irreducible

$k$ -representations of  $G$ , with  $V_0$  the trivial representation  $k$ . The given linear action of  $G$  on  $S$  is induced from an  $n$ -dimensional representation of  $G$  on the space  $V = \mathfrak{n}/\mathfrak{n}^2$  of linear forms.

**5.21 Definition.** The *McKay quiver* of  $G \subseteq \mathrm{GL}(V)$  has

- vertices  $V_0, \dots, V_d$ , and
- $m_{ij}$  arrows  $V_i \longrightarrow V_j$  if the multiplicity of  $V_i$  in an irreducible decomposition of  $V \otimes_k V_j$  is equal to  $m_{ij}$ .

In case  $k$  is algebraically closed, the multiplicities  $m_{ij}$  in the McKay quiver can also be computed from the characters  $\chi, \chi_0, \dots, \chi_d$  for  $V, V_0, \dots, V_d$ ; see [FH91, 2.10]:

$$m_{ij} = \langle \chi_i, \chi \chi_j \rangle = \frac{1}{|G|} \sum_{\sigma \in G} \chi_i(\sigma) \chi(\sigma^{-1}) \chi_j(\sigma^{-1}).$$

For each  $i = 0, \dots, d$ , we set  $P_i = S \otimes_k V_i$ , the corresponding indecomposable projective  $S\#G$ -module. Then in particular  $P_0 = S \otimes_k V_0 = S$ , and  $\{P_0, \dots, P_d\}$  is a complete set of non-isomorphic indecomposable projective  $S\#G$ -modules by Prop. 5.18. The  $V_j$  are simple  $S\#G$ -modules via the surjection  $S\#G \longrightarrow kG$ , with minimal projective cover  $P_j$ . Since  $\mathrm{pd}_{S\#G} V_j \leq n$  by Proposition 5.7, the minimal projective resolution of  $V_j$  over  $S\#G$  thus has the form

$$0 \longrightarrow Q_n^{(j)} \longrightarrow Q_{n-1}^{(j)} \longrightarrow \dots \longrightarrow Q_1^{(j)} \longrightarrow P_j \longrightarrow V_j \longrightarrow 0$$

with projective  $S\#G$ -modules  $Q_i^{(j)}$  for  $i = 1, \dots, n$  and  $j = 0, \dots, d$ .

**5.22 Definition.** The *Gabriel quiver* of  $G \subseteq \mathrm{GL}(V)$  has

- vertices  $P_0, \dots, P_d$ , and
- $m_{ij}$  arrows  $P_i \rightarrow P_j$  if the multiplicity of  $P_i$  in  $Q_1^{(j)}$  is equal to  $m_{ij}$ .

**5.23 Theorem** ([Aus86b]). *The McKay quiver and the Gabriel quiver of  $R$  are isomorphic directed graphs.*

*Proof.* First consider the trivial module  $V_0 = k$ . The minimal  $S\#G$ -resolution of  $k$  was computed in Example 5.9; it is the Koszul complex

$$K.: \quad 0 \rightarrow S \otimes_k \bigwedge^n V \rightarrow \cdots \rightarrow S \otimes_k V \rightarrow S \rightarrow 0.$$

To obtain the minimal  $S\#G$ -resolution of  $V_j$ , we simply tensor the Koszul complex with  $V_j$  over  $k$ , obtaining

$$0 \rightarrow S \otimes_k \left( \bigwedge^n V \otimes_k V_j \right) \rightarrow \cdots \rightarrow S \otimes_k (V \otimes_k V_j) \rightarrow S \otimes_k V_j \rightarrow 0.$$

This displays  $Q_1^{(j)} = S \otimes_k (V \otimes_k V_j)$ , so that the multiplicity of  $P_i$  in  $Q_1^{(j)}$  is equal to that of  $V_i$  in  $V \otimes_k V_j$ .  $\square$

**5.24 Example.** Take  $n = 3$ , and write  $S = k[[x, y, z]]$ . Let  $G = \mathbb{Z}/2\mathbb{Z}$ , with the generator acting on  $V = kx \oplus ky \oplus kz$  by negating each variable. Then  $R = S^G = k[[x^2, xy, xz, y^2, yz, z^2]]$ . There are only two irreducible representations of  $G$ , namely the trivial representation  $k$  and its negative, which is isomorphic to the inverse determinant representation  $V_1 = \det(V)^{-1} = \bigwedge^3 V^*$ . The Koszul complex

$$0 \rightarrow S \otimes \bigwedge^3 V \rightarrow S \otimes_k \bigwedge^2 V \rightarrow S \otimes_k V \rightarrow S \rightarrow 0$$

resolves  $k$ , while the tensor product

$$0 \longrightarrow S \otimes (\wedge^3 V \otimes_k \wedge^3 V^*) \longrightarrow S \otimes_k (\wedge^2 V \otimes_k \wedge^3 V^*) \longrightarrow S \otimes_k (V \otimes_k \wedge^3 V^*) \longrightarrow S \otimes_k \wedge^3 V^* \longrightarrow 0$$

is canonically isomorphic to

$$0 \longrightarrow S \longrightarrow S \otimes_k V^* \longrightarrow S \otimes_k \wedge^2 V^* \longrightarrow S \otimes_k \wedge^3 V^* \longrightarrow 0.$$

Since the given representation  $V = (\wedge^3 V^*)^{(3)}$  is just 3 copies of  $V_1$ , we obtain the McKay quiver

or the Gabriel quiver

Taking fixed points as specified in Corollary 5.20, we find MCM modules

$$M_0 \cong R \quad \text{and} \quad M_1 = (S \otimes_k V_1)^G.$$

Since  $V_1$  is the negative of the trivial representation, the fixed points of  $S \otimes_k V_1$ , with the diagonal action, are generated over  $R$  by those elements  $f \otimes \alpha$  such that  $\sigma(f) = -f$ . These are generated by the linear forms of  $S$ , so that  $M_1$  is the submodule of  $S$  generated by  $(x, y, z)$ . This is isomorphic to the ideal  $(x^2, xy, xz)$  of  $R$ . In particular we recover the obvious  $R$ -direct sum decomposition  $S = R \oplus R(x, y, z)$  of  $S$ .

Observe that  $M_0$  and  $M_1$  are not the only indecomposable MCM  $R$ -modules, even though it turns out that  $R$  does have finite CM type; see Example 15.4.

From now on, we draw the McKay quiver for a group  $G$ , and refer to it as the McKay-Gabriel quiver.

**5.25 Example.** Let  $n = 2$  now, and write  $S = k[[u, v]]$ . Let  $r \geq 2$  be an integer not divisible by  $\text{char}(k)$ , and choose  $0 < q < r$  with  $(q, r) = 1$ . Take  $G = \langle g \rangle \cong \mathbb{Z}/r\mathbb{Z}$  to be the cyclic group of order  $r$  generated by

$$g = \begin{pmatrix} \zeta_r & 0 \\ 0 & \zeta_r^q \end{pmatrix} \in \text{GL}(2, k),$$

where  $\zeta_r$  is a primitive  $r^{\text{th}}$  root of unity. Let  $R = k[[u, v]]^G$  be the corresponding ring of invariants, so that  $R$  is generated by the monomials  $u^a v^b$  satisfying  $a + bq \equiv 0 \pmod{r}$ .

As  $G$  is Abelian, it has exactly  $r$  irreducible representations, each of which is one-dimensional. We label them  $V_0, \dots, V_{r-1}$ , where the generator  $g$  is sent to  $\zeta_r^i$  in  $V_i$ . The given representation  $V$  of  $G$  is isomorphic to  $V_1 \oplus V_q$ , so that for any  $j$  we have

$$V \otimes_k V_j \cong V_{j+1} \oplus V_{j+q},$$

where the indices are of course to be taken modulo  $r$ . The corresponding MCM  $R$ -modules are  $M_j = (S \otimes_k V_j)^G$ , each of which is an  $R$ -submodule of  $S$ :

$$M_j = R \left( u^a v^b \mid a + qb \equiv -j \pmod{r} \right).$$

The general picture is a bit chaotic, so here are a few particular examples.

Take  $r = 5$  and  $q = 3$ . Then  $R = k[[u^5, u^2v, uv^3, v^5]]$ . The McKay-Gabriel

quiver takes the following shape.

The associated indecomposable MCM  $R$ -modules appearing as  $R$ -direct summands of  $S$  are the ideals

$$M_0 = R$$

$$M_1 = R(u^4, uv, v^3) \cong (u^5, u^2v, uv^3)$$

$$M_2 = R(u^3, v) \cong (u^5, u^2v)$$

$$M_3 = R(u^2, uv^2, v^4) \cong (u^5, u^4v^2, u^3v^4)$$

$$M_4 = R(u, v^2) \cong (u^5, u^4v^2).$$

For another example, take  $r = 8, q = 5$ , so that  $R = k[[u^8, u^3v, uv^3, v^8]]$ .

The McKay-Gabriel quiver looks like

and the indecomposable MCM  $R$ -modules arising as direct summands of  $S$

are

$$M_0 = R$$

$$M_1 = R(u^7, u^2v, v^3) \cong (u^8, u^3v, uv^3)$$

$$M_2 = R(u^6, uv, v^6) \cong (u^8, u^3v, u^2v^6)$$

$$M_3 = R(u^5, v) \cong (u^8, u^3v)$$

$$M_4 = R(u^4, u^2v^2, v^4) \cong (u^8, u^6v^2, u^4v^4)$$

$$M_5 = R(u^3, uv^2, v^7) \cong (u^8, u^6v^2, u^5v^7)$$

$$M_6 = R(u^2, u^5v, v^8) \cong (u^2v^6, u^5v^7, v^8)$$

$$M_7 = R(u, v^5) \cong (uv^3, v^8).$$

Finally, take  $r = n + 1$  arbitrary, and  $q = n$ . Then  $R = k[[u^{n+1}, uv, v^{n+1}]] \cong k[[x, y, z]]/(xz - y^{n+1})$  is isomorphic to an  $(A_n)$  hypersurface singularity (see the next chapter). There are  $n + 1$  irreducible representations  $V_0, \dots, V_n$ , and the McKay-Gabriel quiver looks like the one below.

The non-free indecomposable MCM  $R$ -modules take the form

$$M_j = R \left( u^a v^b \mid b - a \equiv j \pmod{n+1} \right)$$

for  $j = 1, \dots, n$ . They have presentation matrices over  $k[[u^{n+1}, uv, v^{n+1}]]$

$$\varphi_j = \begin{pmatrix} (uv)^{n+1-j} & -u^{n+1} \\ -v^{n+1} & (uv)^j \end{pmatrix}$$

or over  $k[[x, y, z]]/(xz - y^{n+1})$

$$\varphi_j = \begin{pmatrix} y^{n+1-j} & -x \\ -z & y^j \end{pmatrix}.$$

## §4 Exercises

**5.26 Exercise.** Let  $k$  be the field with two elements, and define  $\sigma: k[[x]] \rightarrow k[[x]]$  by  $x \mapsto \frac{x}{x+1} = x + x^2 + x^3 + \dots$ . What is the fixed ring of  $\sigma$ ?

**5.27 Exercise.** Let  $R \subseteq S$  be an extension of rings with an *algebra retraction*, that is, a ring homomorphism  $S \rightarrow R$  that restricts to the identity on  $R$ . Prove that  $IS \cap R = I$  for every ideal  $I$  of  $R$ . Conclude that if  $S$  is Noetherian, or local, or complete, then the same holds for  $R$ . (Hint for completeness: If  $\{x_i\}$  is a Cauchy sequence in  $R$  converging to  $x \in S$ , apply Krull's intersection theorem to  $\sigma(x) - x_i$ .)

**5.28 Exercise.** Let  $S$  be an integral domain with an action of a group  $G \subseteq \text{Aut}(S)$ , and set  $R = S^G$ . Let  $F$  and  $K$  be the quotient fields of  $R$  and  $S$ , respectively. Prove that any element of  $K$  can be written as a fraction with denominator in  $R$ , and conclude that  $K^G = F$ .

**5.29 Exercise.** Suppose that  $S$  is a finitely generated algebra over a field  $k$ , let  $G \subseteq \text{Aut}_k(S)$  be a finite group, and set  $R = S^G$ . Prove that  $S$  is finitely generated as an  $R$ -module, and is finitely generated over  $k$ . (Hint: Let  $A \subseteq S$  be the  $k$ -subalgebra generated by the coefficients of the monic polynomials satisfied by the generators of  $S$ , and prove that  $S$  is finitely generated over  $A$ . This argument goes back to Noether [Noe15].)

**5.30 Exercise.** Let  $S$  be a local ring,  $G \subseteq \text{Aut}(S)$  a finite group with order invertible in  $S$ , and  $R = S^G$ .

(i) If  $I \subseteq S$  is a  $G$ -stable ideal, prove that  $(S/I)^G = R/(I \cap R)$ .

(ii) For an element  $s \in S$ , define the *norm* of  $s$  by  $N(s) = \prod_{\sigma \in G} \sigma(s)$ .

Notice that  $N(s) \in R$ . If  $s$  is a non-zerodivisor in  $S$ , show that  $N(s)S \cap R = N(s)R$ .

(iii) Use part (ii) to prove by induction on  $\text{depth } S$  that  $\text{depth } R \geq \text{depth } S$ .

**5.31 Exercise.** Find an example of a non-CM local ring  $S$  and finite group acting such that the fixed ring  $R$  is CM. (There is an example with  $S$  one-dimensional complete local and  $R$  regular.)

**5.32 Exercise.** Let  $S$  and  $G$  be as in 5.1. Show that the fixed-point functor  $-^G$  on  $S\#G$ -modules is exact. (Hint: left-exactness is easy. For right-exactness, take the average of the orbit of any preimage.)

**5.33 Exercise.** Let  $S$  be as in 5.1 and let  $M$  be an  $S$ -module. For each  $\sigma \in G$ , let  ${}^\sigma M$  be the  $S$ -module with the same underlying Abelian group as  $M$ , and structure given by  $s \cdot m = \sigma(s)m$ . Prove that  $S\#G \otimes_S M \cong \bigoplus_{\sigma \in G} {}^\sigma M$ .

**5.34 Exercise.** Prove that in the situation of Proposition 5.7, a finitely generated  $S\#G$ -module  $M$  is projective if and only if it is projective as an  $S$ -module. Conclude that if  $S$  is regular of dimension  $d$ , then  $S\#G$  has global dimension  $d$ .

**5.35 Exercise.** Set  $R = k[[x, y, z]]/(xy)$  and let  $\mathbb{Z}/r\mathbb{Z}$  act on  $R$  by letting the generator take  $(x, y, z)$  to  $(x, \zeta_r y, \zeta_r z)$ , where  $\zeta_r$  is a primitive  $r^{\text{th}}$  root

of unity. Give a presentation for the ring of invariants  $R^G$ . (Cf. Example 13.25.)

**5.36 Exercise.** Set  $R = k[[x, y, z]]/(x^2y - z^2)$ , the two-dimensional ( $D_\infty$ ) complete hypersurface singularity. Let  $r = 2m + 1$  be an odd integer and let  $\mathbb{Z}/r\mathbb{Z}$  act on  $R$  by  $(x, y, z) \mapsto (\zeta_r^2 x, \zeta_r^{-1} y, \zeta_r^{m+2} z)$ , where  $\zeta_r$  is a primitive  $r^{\text{th}}$  root of unity. Find presentations for the ring of invariants  $R^G$  in the cases  $m = 1$  and  $m = 2$ . Try to do  $m = 4$ . (Cf. Example 13.26.)

**5.37 Exercise.** Let  $A$  be a local ring and  $M, N$  two finitely generated  $A$ -modules. Then  $\text{depth Hom}_A(M, N) \geq \min\{2, \text{depth } N\}$ .

**5.38 Exercise.** Let  $\sigma \in \text{GL}(n, k)$  be a pseudo-reflection on  $V = k^{(n)}$ .

1. Let  $v \in V$  span the image of  $\sigma - 1_V$ . Prove that  $\sigma$  is diagonalizable if and only if  $v$  is not fixed by  $\sigma$ .
2. Use Maschke's theorem to prove that if  $|\sigma|$  is relatively prime to  $\text{char}(k)$ , then  $V$  has a decomposition as  $kG$ -modules  $V^\sigma \oplus kv$  and so  $\sigma$  is diagonalizable.

**5.39 Exercise.** If  $k = \mathbb{R}$ , show that any pseudo-reflection has order 2 (so is a *reflection*).

# 6

## *Kleinian singularities and finite CM type*

In the previous chapter we saw that when  $S = k[[x_1, \dots, x_n]]$  is a power series ring endowed with a linear action of a finite group  $G$  whose order is invertible in  $k$ , and  $R = S^G$  is the invariant subring, then the  $R$ -direct summands of  $S$  are MCM  $R$ -modules, and are closely linked to the representation theory of  $G$ . In dimension two, we shall see in this chapter that *every* indecomposable MCM  $R$ -modules is a direct summand of  $S$ . This is due to Herzog [Her78b]. Thus in particular two-dimensional rings of invariants under finite non-modular group actions have finite CM type. In the next chapter we shall prove that in fact every two-dimensional complete normal domain containing  $\mathbb{C}$  and having finite CM type arises in this way.

In the present chapter, we first recall some basic facts on reflexive modules over normal domains, then prove the theorem of Herzog mentioned above. Next we discuss the two-dimensional invariant rings  $k[[u, v]]^G$  that are Gorenstein; by a result of Watanabe [Wat74] these are the ones for which  $G \subseteq \mathrm{SL}(2, k)$ . The finite subgroups of  $\mathrm{SL}(2, \mathbb{C})$  are well-known, their classification going back to Klein, so here we call the resulting invariant rings *Kleinian singularities*, and we derive their defining equations following [Kle93]. It turns out that the resulting equations are precisely the three-variable versions of the ADE hypersurface rings from Chapter 4 §3. This section owes many debts to previous expositions, particularly [Slo83].

In the last two sections, we describe two incarnations of the so-called *McKay correspondence*: first, the identification of the McKay-Gabriel quiver of  $G \subseteq \mathrm{SL}(2, \mathbb{C})$  with the corresponding ADE Coxeter-Dynkin diagram, and then the original observation of McKay that both these are the same as the desingularization graph of  $\mathrm{Spec} k[[u, v]]^G$ .

## §1 Invariant rings in dimension two

In the last chapter we considered invariant rings  $R = k[[x_1, \dots, x_n]]^G$ , where  $G$  is a finite group with order invertible in  $k$  acting linearly on the power series ring  $S = k[[x_1, \dots, x_n]]$ . In general, the direct summands of  $S$  as an  $R$ -module are MCM modules. Here we prove that in dimension two, every indecomposable MCM module is among the  $R$ -direct summands of  $S$ .

First we recall some background on reflexive modules over normal domains. See Chapter 13 for some extensions to the non-normal case.

**6.1 Remarks.** Recall (from, for example, Appendix A) that for a normal domain  $R$ , if a finitely generated  $R$ -module  $M$  is MCM then it is *reflexive*, that is the natural map

$$\sigma_M: M \longrightarrow M^{**} = \mathrm{Hom}_R(\mathrm{Hom}_R(M, R), R),$$

defined by  $\sigma_M(m)(f) = f(m)$ , is an isomorphism. If moreover  $\dim R = 2$ , then the converse holds as well, so that  $M$  is MCM if and only if it is reflexive.

The first assertion of the next proposition is due to Herzog [Her78b], and will imply that two-dimensional rings of invariants have finite CM

type.

**6.2 Proposition.** *Let  $R \rightarrow S$  be a module-finite extension of two-dimensional local rings which satisfy  $(S_2)$  and are Gorenstein in codimension one. Assume that  $R$  is a direct summand of  $S$  as an  $R$ -module. Then every finitely generated reflexive  $R$ -module is a direct summand of a finitely generated reflexive  $S$ -module. If in particular  $R$  is complete and  $S$  has finite CM type, then  $R$  has finite CM type as well.*

*Proof.* Let  $M$  be a reflexive  $R$ -module and set  $M^* = \text{Hom}_R(M, R)$ . Then the split monomorphism  $R \rightarrow S$  induces a split monomorphism  $M = \text{Hom}_R(M^*, R) \rightarrow \text{Hom}_R(M^*, S)$ . Now  $\text{Hom}_R(M^*, S)$  is an  $S$ -module via the action on the codomain, and Exercise 5.37 shows that it satisfies  $(S_2)$  as an  $R$ -module, hence as an  $S$ -module, so is reflexive over  $S$  by Corollary A.15.

Let  $N_1, \dots, N_n$  be representatives for the isomorphism classes of indecomposable MCM  $S$ -modules. Then each  $N_i$  is a MCM  $R$ -module as well, so we write  $N_i = M_{i,1} \oplus \dots \oplus M_{i,m_i}$  for indecomposable MCM  $R$ -modules  $M_{i,j}$ . By the first statement of the Proposition, every indecomposable MCM  $R$ -module is a direct summand of a direct sum of copies of the  $N_i$ , so is among the  $M_{i,j}$  by KRS.  $\square$

**6.3 Theorem.** *Let  $S = k[[u, v]]$  be a power series ring in two variables over a field,  $G$  a finite subgroup of  $\text{GL}(2, k)$  acting linearly on  $S$ , and  $R = S^G$ . Assume that  $R$  is a direct summand of  $S$  as an  $R$ -module. Then every indecomposable finitely generated reflexive  $R$ -module is a direct summand of  $S$  as an  $R$ -module. In particular,  $R$  has finite CM type.*

*Proof.* Let  $M$  be an indecomposable reflexive  $R$ -module. By Proposition 6.2  $M$  is an  $R$ -summand of a reflexive  $S$ -module  $N$ . But  $S$  is regular, so in fact  $N$  is free over  $S$ . Since  $R$  is complete, the KRS Theorem 1.9 implies that  $M$  is a direct summand of  $S$ .  $\square$

The one-one correspondences of Corollary 5.20 can thus be extended in dimension two.

**6.4 Corollary.** *Let  $k$  be a field,  $S = k[[x, y]]$ , and  $G \subseteq \mathrm{GL}(2, k)$  a finite group, with  $|G|$  invertible in  $k$ , acting linearly on  $S$  without pseudo-reflections. Put  $R = S^G$ . Then there are one-one correspondences between*

- *the indecomposable reflexive (MCM)  $R$ -modules;*
- *the indecomposable direct summands of  $S$  as an  $R$ -module;*
- *the indecomposable projective  $\mathrm{End}_R(S)$ -modules;*
- *the indecomposable projective  $S\#G$ -modules; and*
- *the irreducible  $kG$ -modules.*

Observe that while we need the assumption that  $|G|$  be invertible in  $k$  for Corollary 6.4, Proposition 6.2 requires only the weaker assumption that  $R$  be a direct summand of  $S$  as an  $R$ -module. We will make use of this in Remark 6.21 below.

## §2 Kleinian singularities

Having seen the privileged position that dimension two holds in the story so far, we are ready to define and study the two-dimensional hypersurface

rings of finite CM type. These turn out to coincide with a class of rings ubiquitous throughout algebra and geometry, variously called *Kleinian singularities*, *Du Val singularities*, two-dimensional *rational double points*, and other names. Even more, they are the two-dimensional analogues of the ADE hypersurfaces seen in the previous chapter.

For historical reasons, we introduce the Kleinian singularities in a slightly opaque fashion. The rest of the section will clarify matters. For the first part of this chapter, we work over  $\mathbb{C}$  for ease of exposition. We will in the end define the complete Kleinian singularities over any algebraically closed field of characteristic not 2, 3, or 5 (see Definition 6.20).

**6.5 Definition.** A complete complex Kleinian singularity (also rational double point, Du Val singularity) over  $k$  is a ring of the form  $\mathbb{C}[[u, v]]^G$ , where  $G$  is a finite subgroup of  $\mathrm{SL}(2, \mathbb{C})$ .

The reason behind the restriction to  $\mathrm{SL}(2, \mathbb{C})$  rather than  $\mathrm{GL}(2, \mathbb{C})$  as in the previous chapter is the fact, due to Watanabe [Wat74], that  $R = S^G$  is Gorenstein when  $G \subseteq \mathrm{SL}(n, k)$ , and the converse holds if  $G$  is small. Thus the complete Kleinian singularities are the two-dimensional complete Gorenstein rings of invariants of finite group actions.

In order to make sense of this definition, we recall the fact that the finite subgroups of  $\mathrm{SL}(2, \mathbb{C})$  are the “binary polyhedral” groups, which are double covers of the rotational symmetry groups of the Platonic solids, together with two degenerate cases.

The classification of the Platonic solids goes back to Theaetetus around 400 BCE, and is at the center of Plato’s *Timaeus*; the final book of Euclid’s *Elements* is devoted to their properties. According to Bourbaki [Bou02], the

determination of the finite groups of rotations in  $\mathbb{R}^3$  goes back to Hessel, Bravais, and Möbius in the early 19<sup>th</sup> century, though they did not yet have the language of group theory. Jordan [Jor77] was the first to explicitly classify the finite groups of rotations of  $\mathbb{R}^3$ .

**6.6 Theorem.** *The finite subgroups of the group  $SO(3)$ , of rotations of  $\mathbb{R}^3$ , are up to conjugacy the following rotational symmetry groups.*

$C_{n+1}$ : *The cyclic group of order  $n + 1$  for  $n \geq 0$ , the symmetry group of a pyramid (or of a regular plane polygon).*

$D_{n-2}$ : *The dihedral group of order  $2(n-2)$  for  $n \geq 4$ , the symmetry group*

of a beach ball (“hosohedron”).

*T*: The symmetry group of a tetrahedron, which is isomorphic to the alternating group  $A_4$  of order 12.

*O*: the symmetry group of the octahedron, which is isomorphic to the

*symmetric group  $S_4$  of order 24.*

*I: The symmetry group of the icosahedron, which is isomorphic to the alternating group  $A_5$  of order 60.*

In order to leverage this classification into a description of the finite subgroups of  $SL(2, \mathbb{C})$ , we recall some basics of classical group theory. Recall first that the *unitary group*  $U(n)$  is the subgroup of  $GL(n, \mathbb{C})$  consisting of unitary transformations, i.e. those preserving the standard Hermitian dot

product on  $\mathbb{C}^n$ . The *special unitary group*  $SU(n)$  is  $SL(n, \mathbb{C}) \cap U(n)$ . We first observe that to classify the finite subgroups of  $SL(n, \mathbb{C})$ , it suffices to classify those of  $SU(n)$ .

**6.7 Lemma.** *Every finite subgroup of  $GL(n, \mathbb{C})$  (resp.,  $SL(n, \mathbb{C})$ ) is conjugate to a subgroup of  $U(n)$  (resp.,  $SU(n)$ ).*

*Proof.* Let  $G$  be a finite subgroup of  $GL(n, \mathbb{C})$ . Denote the usual Hermitian inner product on  $\mathbb{C}^n$  by  $\langle \cdot, \cdot \rangle$ . It suffices to define a new inner product  $\{ \cdot, \cdot \}$  on  $\mathbb{C}^n$  such that  $\{\sigma u, \sigma v\} = \{u, v\}$  for every  $\sigma \in G$  and  $u, v \in \mathbb{C}^n$ . Indeed, if we find such an inner product, let  $\mathcal{B}$  be an orthonormal basis for  $\{ \cdot, \cdot \}$ , and let  $\rho: \mathbb{C}^n \rightarrow \mathbb{C}^n$  be the change-of-basis operator taking  $\mathcal{B}$  to the standard basis. Then  $\rho G \rho^{-1} \subseteq U(n)$ , as

$$\begin{aligned} \langle \rho \sigma \rho^{-1} u, \rho \sigma \rho^{-1} v \rangle &= \{ \sigma \rho^{-1} u, \sigma \rho^{-1} v \} \\ &= \{ \rho^{-1} u, \rho^{-1} v \} \\ &= \langle u, v \rangle \end{aligned}$$

for every  $\sigma \in G$  and  $u, v \in \mathbb{C}^n$ . Define the desired new product by

$$\{u, v\} = \frac{1}{|G|} \sum_{\sigma \in G} \langle \sigma(u), \sigma(v) \rangle.$$

Then it is easy to check that  $\{ \cdot, \cdot \}$  is again an inner product on  $\mathbb{C}^n$ , and that  $\{\sigma u, \sigma v\} = \{u, v\}$  for every  $\sigma, u, v$ .  $\square$

The special unitary group  $SU(2)$  acts on the complex projective line  $\mathbb{P}_{\mathbb{C}}^1$  by fractional linear transformations (Möbius transformations):

$$\begin{pmatrix} \alpha & -\beta \\ \bar{\beta} & \bar{\alpha} \end{pmatrix} [z : w] = [\alpha z - \beta w : \bar{\beta} z + \bar{\alpha} w].$$

Since the matrices  $\pm I$  act trivially, the action factors through  $\text{PSU}(2) = \text{SU}(2)/\{\pm I\}$ . We claim now that  $\text{PSU}(2) \cong \text{SO}(3)$ , the group of symmetries of the 2-sphere  $S^2$ . Position  $S^2$  with its south pole at the origin, and consider the stereographic projection onto the equatorial plane, which we identify with  $\mathbb{C}$ . Extend this to an isomorphism  $S^2 \rightarrow \mathbb{P}_{\mathbb{C}}^1$  by sending the north pole to the point at infinity. This isomorphism identifies the conformal transformations of  $\mathbb{P}_{\mathbb{C}}^1$  with the rotations of the sphere, and gives a double cover of  $\text{SO}(3)$ .

**6.8 Proposition.** *There is a surjective group homomorphism  $\pi: \text{SU}(2) \rightarrow \text{SO}(3)$  with kernel  $\{\pm I\}$ .*

**6.9 Lemma.** *The only element of order 2 in  $\text{SU}(2)$  is  $-I$ .*

*Proof.* This is a direct calculation using the general form  $\begin{pmatrix} \alpha & -\beta \\ \beta & \alpha \end{pmatrix}$  of an arbitrary element of  $\text{SU}(2)$ . □

**6.10 Lemma.** *Let  $\Gamma$  be a finite subgroup of  $\text{SU}(2)$ . Then either  $\Gamma$  is cyclic of odd order, or  $|\Gamma|$  is even and  $\Gamma = \pi^{-1}(\pi(\Gamma))$  is the preimage of a finite subgroup  $G$  of  $\text{SO}(3)$ .*

*Proof.* If  $\Gamma$  has odd order, then  $-I \notin \Gamma$ , so  $\Gamma \cap \ker \pi = \{I\}$ , and the restriction of  $\pi$  to  $\Gamma$  is an isomorphism of  $\Gamma$  onto its image. By the classification of finite subgroups of  $\text{SO}(3)$ , we see that the only ones of odd order are the cyclic groups  $C_{n+1}$  with  $n+1$  odd. If  $|\Gamma|$  is even, then by Cauchy's Theorem there is an element of order 2 in  $\Gamma$ , which must be  $-I$ . Thus  $\ker \pi \subseteq \Gamma$  and  $\Gamma = \pi^{-1}(\pi(\Gamma))$ . □

**6.11 Theorem.** *The finite non-trivial subgroups of  $\mathrm{SL}(2, \mathbb{C})$ , up to conjugacy, are the following groups, called binary polyhedral groups. Let  $\zeta_r$  denote a primitive  $r^{\mathrm{th}}$  root of unity in  $\mathbb{C}$ .*

$\mathcal{C}_m$ : *The cyclic group of order  $m$  for  $m \geq 2$ , generated by*

$$\begin{pmatrix} \zeta_m & \\ & \zeta_m^{-1} \end{pmatrix}.$$

$\mathcal{D}_m$ : *The binary dihedral group of order  $4m$  for  $m \geq 1$ , generated by  $\mathcal{C}_{2m}$  and*

$$\begin{pmatrix} & i \\ i & \end{pmatrix}.$$

$\mathcal{T}$ : *The binary tetrahedral group of order 24, generated by  $\mathcal{D}_2$  and*

$$\frac{1}{\sqrt{2}} \begin{pmatrix} \zeta_8 & \zeta_8^3 \\ \zeta_8 & \zeta_8^7 \end{pmatrix}.$$

$\mathcal{O}$ : *The binary octahedral group of order 48, generated by  $\mathcal{T}$  and*

$$\begin{pmatrix} \zeta_8^3 & \\ & \zeta_8^5 \end{pmatrix}.$$

$\mathcal{I}$ : *The binary icosahedral group of order 120, generated by*

$$\frac{1}{\sqrt{5}} \begin{pmatrix} \zeta_5^4 - \zeta_5 & \zeta_5^2 - \zeta_5^3 \\ \zeta_5^2 - \zeta_5^3 & \zeta_5 - \zeta_5^4 \end{pmatrix} \quad \text{and} \quad \frac{1}{\sqrt{5}} \begin{pmatrix} \zeta_5^2 - \zeta_5^4 & \zeta_5^4 - 1 \\ 1 - \zeta_5 & \zeta_5^3 - \zeta_5 \end{pmatrix}.$$

**6.12 Theorem.** *The complete complex Kleinian singularities are the rings of invariants of the groups above acting linearly on the power series ring  $S = \mathbb{C}[[u, v]]$ . We name them as follows:*

<i>Singularity Name</i>	<i>Group Name</i>
$A_n$	$\mathcal{C}_{n+1}$ , cyclic ( $n \geq 1$ )
$D_n$	$\mathcal{D}_{n-2}$ , binary dihedral ( $n \geq 4$ )
$E_6$	$\mathcal{T}$ , binary tetrahedral
$E_7$	$\mathcal{O}$ , binary octahedral
$E_8$	$\mathcal{I}$ , binary icosahedral

At this point the naming system is utterly mysterious, but we continue anyway.

It is a classical fact from invariant theory that the Kleinian singularities “embed in codimension one,” that is, are isomorphic to hypersurface rings.<sup>1</sup> We can make this explicit by writing down a set of generating invariants for each of the binary polyhedral groups. These calculations go back to Klein [Kle93], and are also found in Du Val’s book [DV64]; for a more modern treatment see [Lam86]. We like the concreteness of having actual invariants in hand, so we present them here. The details of the derivations are quite involved, so we only sketch them.

**6.13** ( $A_n$ ). In this case, the only monomials fixed by the generator  $(u, v) \mapsto (\zeta_{n+1}u, \zeta_{n+1}^{-1}v)$  are  $uv, u^{n+1}$ , and  $v^{n+1}$ . Thus we set

$$X_{\mathcal{C}}(u, v) = u^{n+1} + v^{n+1} \quad Y_{\mathcal{C}}(u, v) = uv, \quad \text{and} \quad Z_{\mathcal{C}}(u, v) = u^{n+1} - v^{n+1}.$$

<sup>1</sup>Abstractly, we can see this from the connection with Platonic solids as follows [McK01, Dic59]: drawing a sphere around the platonic solid, we project from the north pole to the equatorial plane, which we interpret as  $\mathbb{C}$ . Thus the projection of each vertex  $v$  gives a complex number  $z_v$ , and we form the homogeneous polynomial  $V(x, y) = \prod_v (x - z_v y)$ . Similarly, the center of each edge  $e$  gives a complex number  $z_e$ , and the center of each face  $f$  a corresponding  $z_f$ , which we compile into the polynomials  $E(x, y) = \prod_e (x - z_e y)$  and  $F(x, y) = \prod_f (x - z_f y)$ . These are three functions in two variables, and so there must be a relation  $f(V, E, F) = 0$ .

These generate all the invariants, and satisfy the relation

$$Z_{\mathcal{C}}^2 = X_{\mathcal{C}}^2 - 4Y_{\mathcal{C}}^{n+1}.$$

**6.14** ( $D_n$ ). The subgroup  $\mathcal{C}_{2(n-2)}$  of  $\mathcal{D}_{n-2}$  has invariants  $a = u^{2(n-2)} + v^{2(n-2)}$ ,  $b = uv$ , and  $c = u^{2(n-2)} - v^{2(n-2)}$  as in the case above. The additional generator  $(u, v) \mapsto (iv, iu)$  changes the sign of  $b$ , multiplies  $a$  by  $(-1)^n$ , and sends  $c$  to  $-(-1)^n c$ . Now we have two cases to consider depending on the parity of  $n$ . If  $n$  is even, then  $c$ ,  $a^2$ ,  $ab$ , and  $b^2$  are all fixed, but we can throw out  $b^2$  since  $b^2 = c^2 - 4(a^2)^{n-2}$ . In the other case, when  $n$  is odd, similar considerations imply that the invariants are generated by  $b$ ,  $a^2$ , and  $ac$ . Thus in this case we set

$$\begin{aligned} X_{\mathcal{D}}(u, v) &= u^{2(n-2)} + (-1)^n v^{2(n-2)}, & Y_{\mathcal{D}}(u, v) &= u^2 v^2 \\ Z_{\mathcal{D}}(u, v) &= uv \left( u^{2(n-2)} - (-1)^n v^{2(n-2)} \right). \end{aligned}$$

For these generating invariants we have the relation

$$Z_{\mathcal{D}}^2 = Y_{\mathcal{D}} X_{\mathcal{D}}^2 + 4(-Y_{\mathcal{D}})^{n-1}.$$

**6.15** ( $E_6$ ). The invariants ( $D_4$ ) of the subgroup  $\mathcal{D}_2$  are

$$u^4 + v^4, \quad u^2 v^2, \quad \text{and} \quad uv(u^4 - v^4).$$

The third of these is invariant under the whole group  $\mathcal{T}$ , so we set

$$Y_{\mathcal{T}}(u, v) = uv(u^4 - v^4).$$

Searching for an invariant (or coinvariant) of the form  $P(u, v) = X_{\mathcal{D}} + tY_{\mathcal{D}} = u^4 + tu^2v^2 + v^4$ , we find that if  $t = \sqrt{-12}$ , and we set

$$P(u, v) = u^4 + \sqrt{-12} u^2 v^2 + v^4 \quad \text{and} \quad \bar{P}(u, v) = u^4 - \sqrt{-12} u^2 v^2 + v^4,$$

then

$$X_{\mathcal{F}}(u, v) = P(u, v) \bar{P}(u, v) = u^8 + 14u^4v^4 + v^8$$

is invariant.

Furthermore,  $[\frac{1}{4}(t-2)]^3 = 1$ , so that every linear combination of  $P^3$  and  $\bar{P}^3$  is invariant, such as

$$\begin{aligned} Z_{\mathcal{F}}(u, v) &= \frac{1}{2} [P^3 + \bar{P}^3] \\ &= u^{12} - 33u^8v^4 - 33u^4v^8 + v^{12}. \end{aligned}$$

These three invariants generate all others, and satisfy the relation

$$Z_{\mathcal{F}}^2 = X_{\mathcal{F}}^3 + 108Y_{\mathcal{F}}^4.$$

**6.16** ( $E_7$ ). Begin with the above invariants for  $\mathcal{F}$ . The additional generator for  $\mathcal{O}$  leaves  $X_{\mathcal{F}}$  fixed but changes the signs of  $Y_{\mathcal{F}}$  and  $Z_{\mathcal{F}}$ . We therefore obtain generating invariants

$$X_{\mathcal{O}}(u, v) = Y_{\mathcal{F}}(u, v)^2 = (u^5v - uv^5)^2$$

$$Y_{\mathcal{O}}(u, v) = X_{\mathcal{F}}(u, v) = u^8 + 14v^4v^4 + v^8$$

$$Z_{\mathcal{O}}(u, v) = Y_{\mathcal{F}}(u, v)Z_{\mathcal{F}}(u, v) = uv(u^4 - v^4)(u^{12} - 33u^8v^4 - 33u^4v^8 + v^{12})$$

(of degrees 8, 12, and 18, respectively). These satisfy

$$Z_{\mathcal{O}}^2 = -X_{\mathcal{O}}(108X_{\mathcal{O}}^2 - Y_{\mathcal{O}}^3).$$

**6.17** ( $E_8$ ). From the geometry of the 12 vertices of the icosahedron, Klein derives an invariant of degree 12:

$$\begin{aligned} Y_{\mathcal{I}}(u, v) &= uv(u^5 + \varphi^5v^5)(u^5 - \varphi^{-5}v^5) \\ &= uv(u^{10} + 11u^5v^5 + v^{10}), \end{aligned}$$

where  $\varphi = (1 + \sqrt{5})/2$  is the golden ratio. The Hessian of this form is also invariant, and takes the form  $-121X_{\mathcal{G}}(u, v)$ , where

$$\begin{aligned} X_{\mathcal{G}}(u, v) &= \begin{vmatrix} \partial^2/\partial u^2 & \partial^2/\partial v\partial u \\ \partial^2/\partial u\partial v & \partial^2/\partial v^2 \end{vmatrix} \\ &= (u^{20} + v^{20}) - 228(u^{15}v^5 - u^5v^{15}) + 494u^{10}v^{10}. \end{aligned}$$

The Jacobian of these two forms (i.e. the determinant of the  $2 \times 2$  matrix of partial derivatives) is invariant as well:

$$Z_{\mathcal{G}}(u, v) = (u^{30} + v^{30}) + 522(u^{25}v^5 - u^5v^{25}) - 10005(u^{20}v^{10} + u^{10}v^{20}).$$

Now one checks that<sup>2</sup>

$$Z_{\mathcal{G}}^2 = X_{\mathcal{G}}^3 + 1728Y_{\mathcal{G}}^5.$$

It's interesting to note that in each case above, we have  $\deg X \cdot \deg Y = 2 |G|$ , namely  $2(n+1), 8(n-2), 48, 96, 240$ .

Adjusting the polynomials by certain  $n^{\text{th}}$  roots (of integers at most 5), one obtains the following normal forms for the Kleinian singularities

**6.18 Theorem.** *The complete complex Kleinian singularities are the hypersurface rings defined by the following polynomials in  $\mathbb{C}[[x, y, z]]$ .*

$$(A_n): \quad x^2 + y^{n+1} + z^2, \quad n \geq 1$$

$$(D_n): \quad x^2y + y^{n-1} + z^2, \quad n \geq 4$$

$$(E_6): \quad x^3 + y^4 + z^2$$

$$(E_7): \quad x^3 + xy^3 + z^2$$

<sup>2</sup>tempting one to call  $E_8$  the *great gross singularity* ( $1728 = 12 \times 144$ , a dozen gross, aka a great gross).

$$(E_8): \quad x^3 + y^5 + z^2$$

We summarize the information we have on the Kleinian singularities so far in Table 6.1.

Table 6.1: Complete Kleinian Singularities

Name	$f(x, y, z)$	$G$	$ G $	$(p, q, r)$
$(A_n), n \geq 1$	$x^2 + y^{n+1} + z^2$	$\mathcal{C}_{n+1}$ , cyclic	$n + 1$	$(1, 1, n)$
$(D_n), n \geq 4$	$x^2y + y^{n-1} + z^2$	$\mathcal{D}_{n-2}$ , b. dihedral	$4(n - 2)$	$(2, 2, n - 2)$
$(E_6)$	$x^3 + y^4 + z^2$	$\mathcal{T}$ , b. tetrahedral	24	$(2, 3, 3)$
$(E_7)$	$x^3 + xy^3 + z^2$	$\mathcal{O}$ , b. octahedral	48	$(2, 3, 4)$
$(E_8)$	$x^3 + y^5 + z^2$	$\mathcal{I}$ , b. icosahedral	120	$(2, 3, 5)$

**6.19 Remark.** Now we relax our requirement that we work over  $\mathbb{C}$ . Assume from now on only that  $k$  is an algebraically closed field of characteristic different from 2, 3, and 5.

With this restriction on the characteristic, the groups defined by generators in Theorem 6.11 exist equally well in  $SL(2, k)$ , with two exceptions:  $\mathcal{C}_n$  and  $\mathcal{D}_n$  are not defined if  $\text{char } k$  divides  $n$ . We therefore use the generating invariants  $X, Y$ , and  $Z$  listed in 6.13 and 6.14 to determine the  $(A_{n-1})$  and  $(D_{n+2})$  singularities in positive characteristic. The derivation of the normal forms listed in Theorem 6.18 involves only taking roots of or inverting integers  $a$  for  $a \leq 5$ , so are equally valid for  $\text{char } k \neq 2, 3, 5$ .

**6.20 Definition.** Let  $k$  be an algebraically closed field of characteristic not equal to 2, 3, or 5. The *complete Kleinian singularities over  $k$*  are the

hypersurface rings  $k[[x, y, z]]/(f)$ , where  $f$  is one of the polynomials listed in Theorem 6.18.

**6.21 Remark.** There is one further technicality to address. In the cases  $\mathcal{C}_n$  and  $\mathcal{D}_n$  where  $n$  is divisible by the characteristic of  $k$ , we lose the ability to define the Reynolds operator. However, in each case we can verify that the Kleinian singularity is a direct summand of the regular ring  $k[[u, v]]$  by using the generating invariants  $X$ ,  $Y$ , and  $Z$ .

The case  $(A_{n-1})$  was mentioned in passing already in Example 5.25. Set  $R = k[[u^n, uv, v^n]]$ . Then  $k[[u, v]]$  is isomorphic as an  $R$ -module to  $\bigoplus_{j=0}^{n-1} M_j$ , where  $M_j$  is the  $R$ -span of the monomials  $u^a v^b$  such that  $b - a \equiv j \pmod{n}$ . In particular,  $R$  is a direct summand of  $k[[u, v]]$  in any characteristic.

For the case  $(D_{n+2})$ , we have  $R = k[[u^{2n} + v^{2n}, u^2 v^2, uv(u^{2n} - v^{2n})]]$ . Then  $R$  is a direct summand of  $A = k[[u^{2n}, uv, v^{2n}]]$ : observe that  $A = R \oplus R(uv, u^{2n} - v^{2n})$  and that the second summand is generated by elements negated by  $\tau: (u, v) \mapsto (v, -u)$ . As  $A$  is an  $(A_{2n-1})$  singularity, it is a direct summand of  $k[[u, v]]$  by the previous case.

Combined with Herzog's theorem 6.3, these observations prove the following theorem.

**6.22 Theorem.** *Let  $k$  be an algebraically closed field of characteristic not equal to 2, 3, or 5, and let  $R$  be a complete Kleinian singularity over  $k$ . Then  $R$  has finite CM type.*

### §3 McKay-Gabriel quivers of the Kleinian singularities

In this section we compute the McKay-Gabriel quivers (defined in Chapter 5) for the complete complex Kleinian singularities. We will recover McKay's observation that the underlying graphs of the quivers are exactly the *extended* (also *affine*, or *Euclidean*) Coxeter-Dynkin diagrams  $\tilde{A}_n, \tilde{D}_n, \tilde{E}_6, \tilde{E}_7, \tilde{E}_8$ , corresponding to the name of the singularity from Table 6.1.

For background on the Coxeter-Dynkin diagrams  $A_n, D_n, E_6, E_7, E_8$ , and their extended counterparts  $\tilde{A}_n, \tilde{D}_n, \tilde{E}_6, \tilde{E}_7, \tilde{E}_8$ , we recommend I. Reiten's survey article in the Notices [Rei97]. They have their vertices in far too many pies for us to enumerate. Beyond the connections we will make explicitly in this and the next section, we will content ourselves with the following brief description. The extended ADE diagrams are the finite connected graphs with no loops (a loop is a single edge with both ends at the same vertex) bearing an additive function, i.e. a function  $f$  from the vertices  $\{1, \dots, n\}$  to  $\mathbb{N}$  satisfying  $2f(i) = \sum_j f(j)$  for every  $i$ , where the sum is taken over all neighbors  $j$  of  $i$ . Similarly, the (non-extended) ADE diagrams are the graphs bearing a sub-additive but not additive function, that is, one satisfying  $2f(i) \geq \sum_j f(j)$  for each  $i$ , with strict inequality for at least one  $i$ . The non-extended diagrams are obtained by removing a single distinguished vertex and its incident edges from the extended ADE diagrams.

They're all listed in Table 6.2, with their (sub-)additive functions labeling the vertices. The distinguished vertex to be removed in obtaining the ordinary diagrams from the extended ones is circled. We shall see that,

furthermore, the ranks of the irreducible representations (that is, indecomposable MCM modules) attached to each vertex of the quiver gives the (sub)additive function on the diagram.

Table 6.2: ADE and Extended ADE Diagrams

Recall from Definition 5.21 that the vertices of the McKay-Gabriel quiver of a two-dimensional representation  $G \hookrightarrow \mathrm{GL}(V)$  are the irreducible representations  $V_0, \dots, V_d$  of the group  $G$ , with an arrow  $V_i \rightarrow V_j$  for each copy of  $V_i$  in the direct-sum decomposition of  $V \otimes_k V_j$ . The number of arrows  $V_i \rightarrow V_j$  will (temporarily) be denoted  $m_{ij}$ . Recall that when  $k$  is algebraically closed

$$m_{ij} = \langle \chi_i, \chi \chi_j \rangle = \frac{1}{|G|} \sum_{\sigma \in G} \chi_i(\sigma) \chi(\sigma^{-1}) \chi_j(\sigma^{-1}),$$

where  $\chi, \chi_0, \dots, \chi_d$  are the characters of  $V, V_0, \dots, V_d$ .

**6.23 Lemma.** *Let  $G$  be a finite subgroup of  $\mathrm{SL}(2, \mathbb{C})$  other than the two-element cyclic group. Then  $m_{ij} \in \{0, 1\}$  and  $m_{ij} = m_{ji}$  for all  $i, j = 1, \dots, d$ . In other words, the arrows in the McKay-Gabriel quiver appear in opposed pairs.*

*Proof.* Let  $G$  be one of the subgroups of  $\mathrm{SL}(2, \mathbb{C})$  listed in Theorem 6.11; in particular, the given two-dimensional representation  $V$  is defined by the matrices listed there. By Schur's Lemma and the Hom-tensor adjointness, we have

$$\begin{aligned} m_{ij} &= \dim_{\mathbb{C}} \mathrm{Hom}_{\mathbb{C}G}(V \otimes_{\mathbb{C}G} V_j, V_i) \\ &= \dim_{\mathbb{C}} \mathrm{Hom}_{\mathbb{C}G}(V_j, \mathrm{Hom}_{\mathbb{C}G}(V, V_i)). \end{aligned}$$

The inner Hom has dimension equal to the number of copies of  $V_i$  appearing in the irreducible decomposition of  $V$ . These irreducible decompositions are easily read off from the listed matrices; the only one consisting of two copies of a single irreducible is  $(A_1)$ , which corresponds to the two-element cyclic subgroup  $\mathcal{C}_2$ . Thus  $\mathrm{Hom}_{\mathbb{C}G}(V_i, V)$  has dimension at most 1 for all  $i$ , and so  $m_{ij} \leq 1$  for all  $i, j$ .

Since the trace of a matrix in  $\mathrm{SL}(2, \mathbb{C})$  is the same as that of its inverse, the given representation  $V$  satisfies  $\chi(\sigma^{-1}) = \chi(\sigma)$  for every  $\sigma$ . Thus

$$m_{ij} = \langle \chi_i, \chi \chi_j \rangle = \langle \chi_i \chi, \chi_j \rangle = m_{ji}$$

for every  $i$  and  $j$ . □

In displaying the McKay-Gabriel quivers for the Kleinian singularities, we replace each opposed pair of arrows by a simple edge. This has the effect, thanks to Lemma 6.23, of reducing the quiver to a simple graph with no multiple edges.

**6.24** ( $A_n$ ). We have already calculated the McKay-Gabriel quiver for the ( $A_n$ ) singularities  $xz - y^{n+1}$ , for  $n \geq 1$ , in Example 5.25. Replacing the pairs of arrows there by single edges, we obtain

**6.25** ( $D_n$ ). The binary dihedral group  $\mathcal{D}_{n-2}$  is generated by two elements

$$\alpha = \begin{pmatrix} \zeta_{2(n-2)} & \\ & \zeta_{2(n-2)}^{-1} \end{pmatrix} \quad \text{and} \quad \beta = \begin{pmatrix} & i \\ i & \end{pmatrix}$$

satisfying the relations

$$\alpha^{n-2} = \beta^2 = (\alpha\beta)^2, \quad \text{and} \quad \beta^4 = 1.$$

There are four natural one-dimensional representations as follows:

$$\begin{aligned} V_0 & : \alpha \mapsto 1, & \beta \mapsto 1; \\ V_1 & : \alpha \mapsto 1, & \beta \mapsto -1; \\ V_{n-1} & : \alpha \mapsto -1, & \beta \mapsto i; \\ V_n & : \alpha \mapsto -1, & \beta \mapsto -i. \end{aligned}$$

Furthermore, there is for each  $j = 2, \dots, n-2$  an irreducible two-dimensional representation  $V_j$  given by

$$a \mapsto \begin{pmatrix} \zeta_{2(n-2)}^{j-1} & \\ & \zeta_{2(n-2)}^{-j+1} \end{pmatrix} \quad \text{and} \quad b \mapsto \begin{pmatrix} & i^{j-1} \\ i^{j-1} & \end{pmatrix}.$$

In particular, the given representation  $V$  is isomorphic to  $V_2$ . It's easy to compute now that

$$V \otimes_k V_j \cong V_{j+1} \oplus V_{j-1}$$

for  $2 \leq j \leq n-2$ , leading to the McKay-Gabriel quiver for the  $(D_n)$  singularity.

For the remaining examples, we will take the character table of  $G$  as given (see, for example, [Hum94], [IN99], or [GAP08]). From these data, we will be able to calculate the McKay-Gabriel quiver, since the character of a tensor product is the product of the characters and the irreducible representations are uniquely determined up to equivalence by their characters.

**6.26** ( $E_6$ ). The given presentation of  $\mathcal{T}$  is defined by the generators

$$\alpha = \begin{pmatrix} i & \\ & -i \end{pmatrix}, \quad \beta = \begin{pmatrix} & i \\ i & \end{pmatrix}, \quad \text{and} \quad \gamma = \frac{1}{\sqrt{2}} \begin{pmatrix} \zeta_8 & \zeta_8^3 \\ \zeta_8 & \zeta_8^7 \end{pmatrix}.$$

The character table has the following form.

representative	$I$	$-I$	$\beta$	$\gamma$	$\gamma^2$	$\gamma^4$	$\gamma^5$
class	1	1	6	4	4	4	4
order	1	2	4	6	3	3	6
$V_0$	1	1	1	1	1	1	1
$V_1$	2	-2	0	1	-1	-1	1
$V_2$	3	3	-1	0	0	0	0
$V_3$	2	-2	0	$\zeta_3$	$-\zeta_3$	$-\zeta_3^2$	$\zeta_3^2$
$V_3^\vee$	2	-2	0	$\zeta_3^2$	$-\zeta_3^2$	$-\zeta_3$	$\zeta_3$
$V_4$	1	1	1	$\zeta_3$	$\zeta_3$	$\zeta_3^2$	$\zeta_3^2$
$V_4^\vee$	1	1	1	$\zeta_3^2$	$\zeta_3^2$	$\zeta_3$	$\zeta_3$

Here  $V = V_1$  is the given two-dimensional representation. Now one verifies for example that the character of  $V_1 \otimes_k V_4$ , that is the element-wise product of the second and sixth rows of the table, is equal to the character of  $V_3$ . Hence  $V_1 \otimes_k V_4 \cong V_3$  and the McKay-Gabriel quiver contains an edge connecting  $V_3$  and  $V_4$ . Similarly,  $V_1 \otimes_k V_2 \cong V_1 \oplus V_3 \oplus V_3^\vee$ , so  $V_2$  is a vertex of degree three. Continuing in this way gives the following McKay-Gabriel

quiver.

**6.27.** ( $E_7$ ) The binary octahedral group  $\mathcal{O}$  is generated by  $\alpha$ ,  $\beta$ , and  $\gamma$  from the previous case together with

$$\delta = \begin{pmatrix} \zeta_8^3 & \\ & \zeta_8^5 \end{pmatrix}.$$

This time the character table is as follows.

representative	$I$	$-I$	$\beta$	$\gamma$	$\gamma^2$	$\delta$	$\beta\delta$	$\delta^3$
class	1	1	6	8	8	6	12	6
order	1	2	4	6	3	8	4	8
$V_0$	1	1	1	1	1	1	1	1
$V_1$	2	2	0	1	-1	$-\sqrt{2}$	0	$\sqrt{2}$
$V_2$	3	3	-1	0	0	1	-1	1
$V_3$	4	-4	0	-1	1	0	0	0
$V_4$	3	3	-1	0	0	-1	1	-1
$V_5$	2	-2	0	1	-1	$\sqrt{2}$	0	$-\sqrt{2}$
$V_6$	1	1	1	1	1	-1	-1	-1
$V_7$	2	2	2	-1	-1	0	0	0

Again  $V = V_1$  is the given two-dimensional representation. Now we com-

pute the McKay-Gabriel quiver to be the following.

**6.28.** ( $E_8$ ) Finally, we consider the binary icosahedral group, generated by

$$\sigma = \frac{1}{\sqrt{5}} \begin{pmatrix} \zeta_5^4 - \zeta_5 & \zeta_5^2 - \zeta_5^3 \\ \zeta_5^2 - \zeta_5^3 & \zeta_5 - \zeta_5^4 \end{pmatrix} \quad \text{and} \quad \tau = \frac{1}{\sqrt{5}} \begin{pmatrix} \zeta_5^2 - \zeta_5^4 & \zeta_5^4 - 1 \\ 1 - \zeta_5 & \zeta_5^3 - \zeta_5 \end{pmatrix}.$$

Set  $\varphi^+ = (1 + \sqrt{5})/2$ , the golden ratio, and  $\varphi^- = (1 - \sqrt{5})/2$ . The character table for  $\mathcal{S}$  is below.

representative	$I$	$-I$	$\sigma$	$\tau$	$\tau^2$	$\sigma\tau$	$(\sigma\tau)^2$	$(\sigma\tau)^3$	$(\sigma\tau)^4$
class	1	1	30	20	20	12	12	12	12
order	1	2	4	6	3	10	5	10	5
$V_0$	1	1	1	1	1	1	1	1	1
$V_1$	2	-2	0	1	-1	$\varphi^+$	$-\varphi^-$	$\varphi^-$	$-\varphi^+$
$V_2$	3	3	-1	0	0	$\varphi^+$	$\varphi^-$	$\varphi^-$	$\varphi^+$
$V_3$	4	-4	0	-1	1	1	-1	1	-1
$V_4$	5	5	1	-1	-1	0	0	0	0
$V_5$	6	-6	0	0	0	-1	0	-1	0
$V_6$	4	4	0	1	1	-1	-1	-1	-1
$V_7$	2	-2	0	1	-1	$\varphi^-$	$-\varphi^+$	$\varphi^+$	$-\varphi^-$
$V_8$	3	3	-1	0	0	$\varphi^-$	$\varphi^+$	$\varphi^+$	$\varphi^-$

We find that the McKay-Gabriel quiver is the extended Coxeter-Dynkin

The first direct link between the representation theory of a Kleinian singularity and geometric information is due to G. Gonzalez-Sprinberg and J.-L. Verdier [GSV81]. They constructed, on a case-by-case basis, a one-one correspondence between the irreducible representations of a binary polyhedral group and the irreducible components of the exceptional fiber in a minimal resolution of singularities of the invariant ring. (See below for definitions.) At the end of this section we describe M. Artin and Verdier's direct argument linking MCM modules and exceptional components.

This section is significantly more geometric than other parts of the book; in particular, we omit many of the proofs which would take us too far afield to justify. Most unexplained terminology can be found in [Har77].

Throughout the section,  $(R, \mathfrak{m}, k)$  will be a two-dimensional normal local domain with algebraically closed residue field  $k$ . We do not assume  $\text{char } k = 0$ . Let  $X = \text{Spec } R$ , a two-dimensional affine scheme, that is, a surface. In particular, since  $R$  is normal,  $X$  is regular in codimension one, so  $\mathfrak{m}$  is the unique singular point of  $X$ .

A *resolution of singularities* of  $X$  is a non-singular surface  $Y$  with a proper birational map  $\pi: Y \rightarrow X$  such that the restriction of  $\pi$  to  $Y \setminus \pi^{-1}(\mathfrak{m})$  is an isomorphism. Since  $\dim X = 2$ , resolutions of  $X$  exist as long as  $R$  is excellent [Lip78]. The *geometric genus*  $g(X)$  of  $X$  is the  $k$ -dimension of the first cohomology group  $H^1(Y, \mathcal{O}_Y)$ . This number is finite, and is independent of the choice of a resolution  $Y$ . Again since  $\dim X = 2$ , there is among all resolutions of  $X$  a *minimal resolution*  $\pi: \tilde{X} \rightarrow X$  such that any other resolution factors through  $\pi$ .

**6.30 Definition.** We say that  $X$  and  $R$  have (or are) *rational singularities*

if  $g(X) = 0$ , that is,  $H^1(\tilde{X}, \mathcal{O}_{\tilde{X}}) = 0$ .

We can rephrase this definition in a number of ways. Since  $X = \text{Spec} R$  is affine, the cohomology  $H^i(\tilde{X}, \mathcal{O}_{\tilde{X}})$  is isomorphic to the higher direct image  $R^i \pi_*(\mathcal{O}_{\tilde{X}})$ , so  $R$  has a rational singularity if and only if  $R^1 \pi_*(\mathcal{O}_{\tilde{X}}) = 0$ . This is equivalent to the condition that  $R^i \pi_*(\mathcal{O}_{\tilde{X}}) = 0$  for all  $i \geq 1$ , since the fibers of a resolution  $\pi$  are at most one-dimensional [Har77, III.11.2]. The direct image  $\pi_* \mathcal{O}_{\tilde{X}}$  itself is easy to compute: it is a coherent sheaf of  $R$ -algebras, so  $S = \Gamma(X, \pi_* \mathcal{O}_{\tilde{X}})$  is a module-finite  $R$ -algebra. But since  $\pi$  is birational,  $S$  has the same quotient field as  $R$ . Thus  $S$  is an integral extension, whence equal to  $R$  by normality, and so  $\pi_* \mathcal{O}_{\tilde{X}} = \mathcal{O}_X$ .

Alternatively, recall that the *arithmetic genus* of a scheme  $Y$  is defined by  $p_a(Y) = \chi(\mathcal{O}_Y) - 1$ , where  $\chi$  is the Euler characteristic, defined by the alternating sum of the  $k$ -dimensions of the  $H^i(Y, \mathcal{O}_Y)$ . It follows from the Leray spectral sequence, for example, that if  $\pi: \tilde{X} \rightarrow X$  is a resolution of singularities, then

$$p_a(X) - p_a(\tilde{X}) = \dim_k H^1(\tilde{X}, \mathcal{O}_{\tilde{X}}),$$

so that  $X$  is a rational singularity if and only if the arithmetic genus of  $X$  is not changed by resolving the singularity.

For a more algebraic criterion, assume momentarily that  $R$  is a non-negatively graded ring over a field  $R_0 = k$  of characteristic zero. Flenner [Fle81] and Watanabe [Wat83] independently proved that  $R$  has a rational singularity if and only if the *a-invariant*  $a(R)$  is negative. In general,  $a(R)$  is the largest  $n$  such that the  $n^{\text{th}}$  graded piece of the local cohomology module  $H_m^{\dim R}(R)$  is non-zero. For a two-dimensional weighted-

homogeneous hypersurface singularity such as the Kleinian singularities in Theorem 6.18, the definition is particularly easy to apply:

$$a(k[x, y, z]/(f)) = \deg f - \deg x - \deg y - \deg z.$$

In particular, we check from Table 6.1 that the Kleinian singularities have rational singularities in characteristic zero.

More generally, any two-dimensional quotient singularity  $k[u, v]^G$  or  $k[[u, v]]^G$ , where  $G$  is a finite group with  $|G|$  invertible in  $k$ , has rational singularities [Bur74, Vie77]. In fact, the restriction on  $|G|$  is unnecessary for the Kleinian singularities: if  $S$  has rational singularities and  $R$  is a subring of  $S$  which is a direct summand as  $R$ -module, then  $R$  has rational singularities [Bou87]. Thus the Kleinian singularities have rational singularities in any characteristic in which they are defined.

As a final bit of motivation for the study of rational surface singularities, we point out that a normal surface  $X = \text{Spec } R$  is a rational singularity if and only if the divisor class group  $\text{Cl}(R)$  is finite, if and only if  $R$  has only finitely many rank-one MCM modules up to isomorphism [Mum61, Lip69].

Return now to our two-dimensional normal domain  $R$ , its spectrum  $X$ , and  $\pi: \tilde{X} \rightarrow X$  the minimal resolution of singularities. With  $0 \in X$  the unique singular point of  $X$ , set  $E = \pi^{-1}(0)$ , the *exceptional fiber* of  $\pi$ . Then  $E$  is connected by Zariski's Main Theorem [Har77, III.5.2], and is one-dimensional since  $\pi$  is birational. In other words,  $E$  is a union of irreducible curves on  $\tilde{X}$ , so we write  $E = \bigcup_{i=1}^n E_i$ .

**6.31 Lemma** ([Bri68, Lemma 1.3]). *Let  $\pi: \tilde{X} \rightarrow X$  be the minimal resolution of a rational singularity  $X$ , and let  $E = \bigcup_{i=1}^n E_i$  be the exceptional*

fiber.

- (i) Each  $E_i$  is non-singular, in particular reduced, and furthermore is a rational curve, i.e.  $E_i \cong \mathbb{P}^1$ .
- (ii)  $E_i \cap E_j \cap E_k = \emptyset$  for pairwise distinct  $i, j, k$ .
- (iii)  $E_i \cap E_j$  is either empty or a single reduced point for  $i \neq j$ , that is, the  $E_i$  meet transversely if at all.
- (iv)  $E$  is cycle-free.

To describe the intersection properties of the exceptional curves more precisely, recall a bit of the intersection theory of curves on non-singular surfaces. Let  $C$  and  $D$  be curves on  $\tilde{X}$  with no common component. The *intersection multiplicity* of  $C$  and  $D$  at a closed point  $x \in \tilde{X}$  is the length of the quotient  $\mathcal{O}_{\tilde{X},x}/(f,g)$ , where  $f=0$  and  $g=0$  are local equations of  $C$  and  $D$  at  $x$ . The *intersection number*  $C \cdot D$  of  $C$  and  $D$  is the sum of intersection multiplicities at all common points  $x$ . The *self-intersection*  $C^2$ , a special case, is defined to be the degree of the normal bundle to  $C$  in  $\tilde{X}$ . Somewhat counter-intuitively, this can be negative; see [Har77, V.1.9.2] for an example.

The first part of the next theorem is due to Du Val [DV34] and Mumford [Mum61, Hir95a]; it immediately implies the second and third parts [Art66, Prop. 2 and Thm. 4].

**6.32 Theorem.** *Let  $\pi: \tilde{X} \rightarrow X$  be the minimal resolution of a surface singularity (not necessarily rational) with exceptional fiber  $E = \bigcup_{i=1}^n E_i$ . Define the intersection matrix of  $X$  to be the symmetric matrix  $E(X)_{ij} = (E_i \cdot E_j)$ .*

- (i) The matrix  $E(X)$  is negative definite with off-diagonal entries either 0 or 1.
- (ii) There exist positive divisors supported on  $E$  (that is, divisors of the form  $Z = \sum_{i=1}^n m_i E_i$  with  $m_i \geq 1$  for all  $i$ ) such that  $Z \cdot E_i \leq 0$  for all  $i$ .
- (iii) Among all such  $Z$  as in (ii), there is a unique smallest one, which is called the fundamental divisor of  $X$  and denoted  $Z_f$ .

To find the fundamental divisor there is a straightforward combinatorial algorithm: begin with  $m_i = 1$  for all  $i$ , so that  $Z_1 = \sum_i E_i$ . If  $Z_1 \cdot E_i \leq 0$  for each  $i$ , we set  $Z_f = Z_1$  and stop; otherwise  $Z_1 \cdot E_j > 0$  for some  $j$ . In that case, we put  $Z_2 = Z_1 + E_j$  and continue. The process terminates by the negative definiteness of the matrix  $E(X)$ . See below for two examples.

For a rational singularity, we can identify  $Z_f$  more precisely, and this will allow us to identify the Gorenstein rational singularities.

**6.33 Proposition** ([Art66, Thm 4]). *The fundamental divisor  $Z_f$  of a surface  $X$  with a rational singularity satisfies*

$$(\mathcal{O}_{\tilde{X}} \otimes_{\mathcal{O}_X} \mathfrak{m})/\text{torsion} = \mathcal{O}_{\tilde{X}}(-Z_f).$$

*In particular, we have formulas for the multiplicity and the embedding dimension  $\mu_R(\mathfrak{m})$  of  $R$ :*

$$\begin{aligned} e(R) &= -Z_f^2 \\ \text{embdim}(R) &= -Z_f^2 + 1 \end{aligned}$$

**6.34 Corollary.** *A two-dimensional normal local domain  $R$  with a rational singularity has minimal multiplicity [Abh67]:*

$$e(R) = \mu_R(\mathfrak{m}) - \dim R + 1.$$

**6.35 Corollary.** *Let  $(R, \mathfrak{m})$  be a two-dimensional normal local domain, and assume that  $R$  is Gorenstein. If  $R$  is a rational singularity, then  $R$  is a hypersurface ring of multiplicity two.*

Isolated singularities of multiplicity two are often called “double points.”

*Proof.* By the Proposition, we have  $e(R) = -Z_f^2$  and  $\mu_R(\mathfrak{m}) = -Z_f^2 + 1$ . Cut down by a regular sequence of length two in  $\mathfrak{m} \setminus \mathfrak{m}^2$  to arrive at an Artinian local ring  $\bar{R}$  with  $e(\bar{R}) = \ell(\bar{R})$  and  $\mu_{\bar{R}}(\bar{\mathfrak{m}}) = \mu_R(\mathfrak{m}) - 2$ . These together imply that  $\mu_{\bar{R}}(\bar{\mathfrak{m}}) = \ell(\bar{R}) - 1$ , so the Hilbert function of  $\bar{R}$  is  $(1, -Z_f^2 - 1, 0, \dots)$ . However,  $\bar{R}$  is Gorenstein, so has socle dimension equal to 1. This forces  $Z_f^2 = -2$ , which gives  $e(R) = 2$  and  $\mu_R(\mathfrak{m}) = 3$ . In particular  $R$  is a hypersurface ring.  $\square$

**6.36 Corollary.** *Let  $R$  be a Gorenstein rational surface singularity. The self-intersection number  $E_i^2$  of each exceptional component is  $-2$ . Equivalently the normal bundle  $\mathcal{N}_{E_i/\tilde{X}}$  is  $\mathcal{O}_{E_i}(-2)$ .*

*Proof.* This is a straightforward calculation using the adjunction formula and Riemann-Roch Theorem, see [Dur79, A3], together with  $Z_f^2 = -2$ .  $\square$

**6.37 Remark.** At this point, we can describe the connection between Gorenstein rational surface singularities and the ADE Coxeter-Dynkin diagrams. To do this, we define the *desingularization graph* of a surface  $X$  to be the

dual graph of the exceptional fiber in a minimal resolution of singularities. Precisely, let  $\pi: \tilde{X} \rightarrow X$  be the minimal resolution of singularities, and let  $E_1, \dots, E_n$  be the irreducible components of the exceptional fiber. Then the desingularization graph has vertices  $E_1, \dots, E_n$ , with an edge joining  $E_i$  to  $E_j$  for  $i \neq j$  if and only if  $E_i \cap E_j \neq \emptyset$ .

Let  $Z_f = \sum_i m_i E_i$  be the fundamental divisor of  $X$ , and define a function  $f$  from the vertices  $\{E_1, \dots, E_n\}$  to  $\mathbb{N}$  by  $f(E_i) = m_i$ . Then for  $i = 1, \dots, n$  we have

$$0 \geq Z \cdot E_i = -2m_i + \sum_j m_j (E_i \cdot E_j) = -2m_i + \sum_j m_j,$$

where the sum is over all  $j \neq i$  such that  $E_i \cap E_j \neq \emptyset$ . This gives  $2f(E_i) \geq \sum_j f(E_j)$ , and the negative definiteness of the intersection matrix (Theorem 6.32) implies that  $f$  is a sub-additive, non-additive function on the graph. Thus the graph is ADE.

We illustrate the general facts described so far with two examples of resolutions of rational double points: the  $(A_1)$  and  $(D_4)$  hypersurfaces. We will also draw the desingularization graphs for these two examples.

**6.38 Example.** Let  $X$  be the hypersurface in  $\mathbb{A}^3$  defined by the  $(A_1)$  polynomial  $x^2 + y^2 + z^2$ . To resolve the singularity of  $X$  at the origin, we blow up the origin in  $\mathbb{A}^3$ . Precisely, we set

$$\tilde{\mathbb{A}}^3 = \{((x, y, z), (a : b : c)) \in \mathbb{A}^3 \times \mathbb{P}^2 \mid xb = ya, xc = za, yc = zb\}.$$

(See [Har77] for basics on blowups.) The projection  $\varphi: \tilde{\mathbb{A}}^3 \rightarrow \mathbb{A}^3$  is an isomorphism away from the origin in  $\mathbb{A}^3$ , while  $\varphi^{-1}(0, 0, 0)$  is the projective plane  $\mathbb{P}^2 \subseteq \tilde{\mathbb{A}}^3$ .

Let  $\tilde{X}$  be the blowup of  $X$  at the origin. That is,  $\tilde{X}$  is the Zariski closure of  $\varphi^{-1}(X \setminus (0,0,0))$  in  $\tilde{\mathbb{A}}^3$ . Then  $\tilde{X}$  is defined in  $\tilde{\mathbb{A}}^3$  by the vanishing of  $a^2 + b^2 + c^2$ . The restriction of  $\varphi$  gives  $\pi: \tilde{X} \rightarrow X$ , and the exceptional fiber  $E$  is the preimage of  $(0,0,0)$  in  $\tilde{X}$ . We claim that  $\tilde{X}$  is smooth, and that  $E$  is a single projective line  $\mathbb{P}^1$ .

The blowup  $\tilde{X}$  is covered by three affine charts  $U_a, U_b, U_c$ , defined by  $a \neq 0, b \neq 0, c \neq 0$  respectively, or equivalently by  $a = 1, b = 1, c = 1$ . In the chart  $U_a$ , we have  $y = xb$  and  $z = xc$ , so that the defining equation of  $X$  becomes

$$x^2 + x^2b^2 + x^2c^2 = x^2(1 + b^2 + c^2)$$

Above  $X \setminus (0,0,0)$ , we have  $x \neq 0$ , so the preimage of  $X \setminus (0,0,0)$  is defined by  $x \neq 0$  and  $1 + b^2 + c^2 = 0$ . The Zariski closure of  $\varphi^{-1}(X \setminus (0,0,0))$  is thus in this chart the cylinder  $1 + b^2 + c^2 = 0$  in  $U_a \cong \mathbb{A}^3$ . Since all three charts are symmetric, we conclude that  $\tilde{X}$  is smooth.

Remaining in the chart  $U_a$ , we see that the exceptional fiber  $E$  is defined in  $\tilde{X}$  by  $x = 0$ , so is defined in  $U_a$  by  $1 + b^2 + c^2 = 0$ . Again we use the symmetry of the three charts to conclude that  $E$  is smooth, and even rational, so  $E \cong \mathbb{P}^1$ .

Drawing the desingularization graph of  $X$  is thus quite trivial: it has a single node and no edges.

$$E$$

Observe that this is the  $(A_1)$  Coxeter-Dynkin diagram. Since  $E^2 = -2$  by Corollary 6.36, we find that  $Z_f = E$  is the fundamental divisor.

**6.39 Example.** For a slightly more sophisticated example, consider the  $(D_4)$  hypersurface  $X \subseteq \mathbb{A}^3$  defined by the vanishing of  $x^2y + y^3 + z^2$ . Again

blowing up the origin in  $\mathbb{A}^3$ , we obtain as before

$$\tilde{\mathbb{A}}^3 = \{((x, y, z), (a : b : c)) \in \mathbb{A}^3 \times \mathbb{P}^2 \mid xb = ya, xc = za, yc = zb\},$$

with projection  $\varphi: \tilde{\mathbb{A}}^3 \rightarrow \mathbb{A}^3$ . This time let  $X_1$  be the Zariski closure of  $\varphi^{-1}(X \setminus (0, 0, 0))$ . In the affine chart  $U_a$  where  $a = 1$ , we again have  $y = xb$  and  $z = xc$ , so the defining polynomial becomes

$$x^3b + x^3b^3 + x^2c^2 = x^2(x(b + b^3) + c^2).$$

Thus  $X_1$  is defined by  $x(b + b^3) + c^2$  in  $U_a$ , so is a *singular* surface. In fact, an easy change of variables reveals that in this chart  $X_1$  is isomorphic to an  $(A_1)$  hypersurface singularity (in the variables  $\frac{1}{2}(x + (b + b^3))$ ,  $\frac{i}{2}(x - (b + b^3))$ , and  $c$ ). In particular,  $X_1$  has three singular points, with coordinates  $x = c = 0$  and  $b + b^3 = 0$ . In the coordinates of  $\tilde{\mathbb{A}}^3$ , they are at  $((0, 0, 0), (1 : b : 0))$ , where  $b^3 = -b$ . The exceptional fiber, which we denote  $E_1$ , corresponds in this chart to  $x = 0$ , whence  $c = 0$ , so is just the  $b$ -axis.

In the other charts, we find no further singularities. On  $U_b$ , the defining polynomial is

$$y^3a + y^3 + y^2c^2 = y^2(ya + y + c^2)$$

so that  $X_1$  is defined in  $U_b$  by  $ya + y + c^2 = 0$ . This is also an  $(A_1)$  singularity, this time with a single singular point at  $y = c = 0$ . However, we've already seen this point, as its  $\tilde{\mathbb{A}}^3$  coordinates are  $((0, 0, 0), (-1 : 1 : 0))$ , which is in  $U_a$ . The exceptional fiber here is the  $a$ -axis. Finally, in the chart  $U_c$ , we find

$$z^3a^2b + z^3b^3 + z^2 = z^2(za^2b + zb^3 + 1)$$

so that  $X_1$  is smooth in this chart and  $E_1$  is not visible. In particular we find that  $E_1 \cong \mathbb{P}^1$ .

Since the first blowup  $X_1$  is not smooth, we continue, resolving the singularities of the surface  $x(b + b^3) + c^2 = 0$  by blowing up its three singular points. Since each singular point is locally isomorphic to an  $(A_1)$  hypersurface, we appeal to the previous example to see that the resulting surface  $\tilde{X}$  is smooth, and that each of the three new exceptional fibers  $E_2, E_3, E_4$  intersects the original one  $E_1$  transversely. The desingularization graph thus has the shape of the  $(D_4)$  Coxeter-Dynkin diagram:

To compute the fundamental divisor  $Z_f$ , we begin with  $Z_1 = E_1 + E_2 + E_3 + E_4$ . Since  $E_i^2 = -2$  and  $E_j \cdot E_1 = 1$  for each  $j = 2, 3, 4$ , we find

$$Z_1 \cdot E_1 = -2 + 1 + 1 + 1 = 1 > 0.$$

Thus we replace  $Z_1$  by  $Z_2 = 2E_1 + E_2 + E_3 + E_4$ . Now

$$Z_2 \cdot E_1 = -4 + 1 + 1 + 1 \leq 0,$$

and for  $j = 2, 3, 4$  we have  $Z_2 \cdot E_j = 2 - 2 + 0 + 0 \leq 0$ , so that  $Z_f = Z_2 = 2E_1 + E_2 + E_3 + E_4$  is the fundamental divisor.

The calculations in the examples can be carried out for each of the Kleinian singularities in Table 6.1, and one verifies the next result, which was McKay's original observation.

**6.40 Theorem (McKay).** *Let  $G$  be a finite subgroup of  $SL(2, \mathbb{C})$  and let  $R = \mathbb{C}[[u, v]]^G$  be the corresponding ring of invariants. Then the desingularization graph of  $X = \text{Spec} R$  is an ADE Coxeter-Dynkin diagram. In*

particular, it is equal to the McKay-Gabriel quiver of  $G$  with the vertex corresponding to the trivial representation removed. Furthermore, the coefficients of the fundamental divisor  $Z_f$  coincide with the dimensions of the corresponding irreducible representations of  $G$ , and with the ranks of the corresponding indecomposable MCM  $R$ -modules.

We can now state the theorem of Artin and Verdier on the geometric McKay correspondence. Here is the notation in effect through the end of the section:

**6.41 Notation.** Let  $(R, \mathfrak{m}, k)$  be a complete local normal domain of dimension two, which is a rational singularity. Let  $\pi: \tilde{X} \rightarrow X = \text{Spec} R$  be its minimal resolution of singularities, and  $E = \pi^{-1}(\mathfrak{m})$  the exceptional fiber, with irreducible components  $E_1, \dots, E_n$ . Let  $Z_f = \sum_i m_i E_i$  be the fundamental divisor of  $X$ . We identify a reflexive  $R$ -module  $M$  with the associated coherent sheaf of  $\mathcal{O}_X$ -modules, and define the *strict transform* of  $M$  by

$$\tilde{M} = (M \otimes_{\mathcal{O}_X} \mathcal{O}_{\tilde{X}}) / \text{torsion},$$

a sheaf on  $\tilde{X}$ .

**6.42 Theorem (Artin-Verdier).** *With notation as above, assume moreover that  $R$  is Gorenstein. Then there is a one-one correspondence, induced by the first Chern class  $c_1(-)$ , between indecomposable non-free MCM  $R$ -modules and irreducible components  $E_i$  of the exceptional fiber. Precisely: Let  $M$  be an indecomposable non-free MCM  $R$ -module, and let  $[C] = c_1(\tilde{M}) \in \text{Pic}(\tilde{X})$ . Then there is a unique index  $i$  such that  $C \cdot E_i = 1$  and  $C \cdot E_j = 0$  for  $i \neq j$ . Furthermore, we have  $\text{rank}_R(M) = C \cdot Z_f = m_i$ .*

The first Chern class mentioned in the Theorem is a mechanism for turning a locally free sheaf  $\mathcal{E}$  into a divisor  $c_1(\mathcal{E})$  in the Picard group  $\text{Pic}(\tilde{X})$ . In particular,  $c_1(-)$  is additive on short exact sequences over  $\tilde{X}$ .

The main ingredients of the proof of Theorem 6.42 are compiled in the next propositions.

**6.43 Proposition.** *With notation as in 6.41,  $\tilde{M}$  enjoys the following properties.*

(i)  $\tilde{M}$  is a locally free  $\mathcal{O}_{\tilde{X}}$ -module, generated by its global sections.

(ii)  $\Gamma(\tilde{X}, \tilde{M}) = M$  and  $H^1(\tilde{X}, \tilde{M}^*) = 0$ .

(iii) *There is a short exact sequence of sheaves on  $\tilde{X}$*

$$(6.43.1) \quad 0 \longrightarrow \mathcal{O}_{\tilde{X}}^{(r)} \longrightarrow \tilde{M} \longrightarrow \mathcal{O}_C \longrightarrow 0,$$

where  $r = \text{rank}_R(M)$ , and  $C$  is a closed one-dimensional subscheme of  $\tilde{X}$  which meets the exceptional fiber  $E$  transversely. Furthermore, the global sections of (6.43.1) give an exact sequence of  $R$ -modules

$$(6.43.2) \quad 0 \longrightarrow R^{(r)} \longrightarrow M \longrightarrow \Gamma(\tilde{X}, \mathcal{O}_C) \longrightarrow 0$$

Observe that the class  $[C]$  of the curve  $C$  in the Picard group  $\text{Pic}(\tilde{X})$  is equal to the first Chern class  $c_1(\tilde{M})$  of  $\tilde{M}$ , since  $c_1(-)$  is additive on short exact sequences and  $c_1(\mathcal{L}) = [\mathcal{L}] \in \text{Pic}(\tilde{X})$  for any line bundle  $\mathcal{L}$ .

**6.44 Proposition.** *Keep all the notation of 6.41, and assume moreover that  $R$  is Gorenstein. Fix a reflexive  $R$ -module  $M$ , and let  $C$  be the curve guaranteed by Prop. 6.43. Then*

- (i)  $C \cdot Z_f \leq r$ , with equality if and only if  $M$  has no non-trivial free direct summands.
- (ii) If  $C = C_1 \cup \cdots \cup C_s$  is the decomposition of  $C$  into irreducible components, then  $M$  can be decomposed accordingly:  $M \cong M_1 \oplus \cdots \oplus M_s$ , with each  $M_i$  indecomposable and  $c_1(\widetilde{M}_i) = [C_i]$  for each  $i$ .

The proofs of Propositions 6.43 and 6.44 are relatively straightforward algebraic geometry. The key observation giving the existence of the short exact sequence (6.43.1) is a general-position argument:  $r$  generically chosen sections of  $\widetilde{M}$  generate a free subsheaf  $\mathcal{O}_{\widetilde{X}}^{(r)}$ , and one checks that the choice can be made so that the restriction of the kernel to each  $E_i$  is isomorphic to a direct sum of residue fields at points distinct from each other and from the intersections  $E_i \cap E_j$ . The statements in Proposition 6.44 follow from the fact that  $Z_f \cdot C$  is equal to the minimal number of generators of the  $R$ -module  $\Gamma(\widetilde{X}, \mathcal{O}_C)$  by Proposition 6.33, together with duality for the proper map  $\pi$ .

## §5 Exercises

**6.45 Exercise.** In the setup of Proposition 6.2, prove that if  $M$  is a reflexive  $R$ -module such that  $\text{Ext}_R^i(M^*, S) = 0$  for  $i = 1, \dots, n-2$ , then  $M \in \text{add}_R(S)$ .

**6.46 Exercise.** Let  $R$  be a reduced Noetherian ring and  $M, N, P$  finitely generated reflexive  $R$ -modules. Define the *reflexive product* of  $M$  and  $N$  by

$$M \cdot N = (M \otimes_R N)^{**}$$

Prove the following isomorphisms.

- (i)  $M \cdot N \cong N \cdot M$ .
- (ii)  $\text{Hom}_R(M \cdot N, P) \cong \text{Hom}_R(M, \text{Hom}_R(N, P))$ .
- (iii)  $M \cdot (N \cdot P) \cong (M \cdot N) \cdot P$ .

**6.47 Exercise.** Let  $(R, \mathfrak{m})$  be a reduced CM local ring of dimension two,  $X = \text{Spec}R$ ,  $U = X \setminus \{\mathfrak{m}\}$ , and  $i: U \rightarrow X$  the open embedding. Let  $M \mapsto \widetilde{M}$  and  $\mathcal{F} \mapsto \Gamma(\mathcal{F})$  be the usual sheafification and global section functors between  $R$ -modules and coherent sheaves on  $X$ .

- (i) If  $M$  is MCM, then the natural map  $M \rightarrow \Gamma(i_* i^* \widetilde{M})$  is an isomorphism. (Use the exact sequence  $0 \rightarrow H_{\mathfrak{m}}^0(M) \rightarrow M \rightarrow \Gamma(i_* i^* \widetilde{M}) \rightarrow H_{\mathfrak{m}}^1(M) \rightarrow 0$ .)
- (ii) If  $M$  is torsion-free,  $M^{**} \rightarrow \Gamma(i_* i^* \widetilde{M})$  is an isomorphism. (Use the case above and  $\lambda(T) < \infty$ . Notice  $i^*$  is exact since  $i$  is an open embedding, and  $i^*T = 0$ , so get a square relating  $M$  to  $M^{**}$  and  $\widetilde{M^{**}}$ .)
- (iii) Assume  $R$  is normal, and let  $\text{VB}(U)$  be the category of locally free  $\mathcal{O}_U$ -modules. Then  $i^*: \text{CM}(R) \rightarrow \text{VB}(U)$  is an equivalence.
- (iv)  $R$  as in the previous one,  $i^*(M \cdot N) \cong i^*M \otimes_{\mathcal{O}_U} i^*N$ .

**6.48 Exercise.** Let  $(R, \mathfrak{m}, k)$  be a CM local ring. Prove that  $e(R) \geq \mu_R(\mathfrak{m}) - \dim R + 1$ .

**6.49 Exercise.** Generalize Corollary 6.35 by showing that any Gorenstein local ring  $(R, \mathfrak{m}, k)$  satisfying  $e(R) = \mu_R(\mathfrak{m}) - \dim R + 1$  is a hypersurface of multiplicity two.

**6.50 Exercise.** Classify the finite subgroups of  $GL(2, \mathbb{C})$  by using the surjection  $\mathbb{C}^* \times SL(2, \mathbb{C}) \rightarrow GL(2, \mathbb{C})$  sending  $(d, \sigma)$  to  $d\sigma$ .

**6.51 Exercise.** Let  $G = \langle \sigma \rangle$  be a finite cyclic subgroup of  $GL(2, \mathbb{C})$ . Show that the ring of invariants  $\mathbb{C}[[u, v]]^G$  is generated by two invariants if and only if  $\sigma$  has an eigenvalue equal to 1.

# *Isolated singularities and classification in dimension two*

In this chapter we present a pair of celebrated theorems due originally to Auslander. The first, Theorem 7.12, states that a CM local ring of finite CM type has at most an isolated singularity. We give the simplified proof due to Huneke and Leuschke, which requires some easy general preliminaries on elements of  $\text{Ext}^1$ . The second, Theorem 7.19, gives a strong converse to Herzog's Theorem 6.3, namely that in dimension two over a field of characteristic zero, every CM complete local algebra having finite CM type is a ring of invariants.

## §1 Miyata's theorem

The classical Yoneda correspondence (see [ML95]) allows us to identify elements of an Ext-module  $\text{Ext}_R^i(M, N)$  as equivalence classes of  $i$ -fold extensions of  $N$  by  $M$ . In the case  $i = 1$ , this is particularly simple: an element  $\alpha \in \text{Ext}_R^1(M, N)$  is an equivalence class of short exact sequences  $0 \rightarrow N \rightarrow X \rightarrow M \rightarrow 0$ , where we declare two such sequences, with middle terms  $X, X'$ , to be equivalent if they fit into a commutative diagram

$$(7.0.1) \quad \begin{array}{ccccccc} 0 & \longrightarrow & N & \longrightarrow & X & \longrightarrow & M \longrightarrow 0 \\ & & \parallel & & \downarrow & & \parallel \\ 0 & \longrightarrow & N & \longrightarrow & X' & \longrightarrow & M \longrightarrow 0. \end{array}$$

as in (7.0.1).

It follows from the Snake Lemma that in this situation  $X \cong X'$ , so the middle term  $X_\alpha$  is determined by the element  $\alpha$ . The converse is false (cf. Exercise 7.22), but Miyata's Theorem [Miy67] gives a partial converse: if a short exact sequence “looks” split—the middle term is isomorphic to the direct sum of the other two—then it is split.

**7.1 Theorem** (Miyata). *Let  $R$  be a commutative Noetherian ring and let*

$$\alpha: \quad N \xrightarrow{p} X_\alpha \xrightarrow{q} M \longrightarrow 0$$

*be an exact sequence of finitely generated  $R$ -modules. If  $X_\alpha \cong M \oplus N$ , then  $\alpha$  is a split short exact sequence.*

*Proof.* It suffices to show that  $p: N \rightarrow X_\alpha$  is a *pure* homomorphism, that is,  $Z \otimes_R p: Z \otimes_R N \rightarrow Z \otimes_R X_\alpha$  is injective for every finitely generated  $R$ -module  $Z$ . Indeed, taking  $Z = R$  will show that  $p$  is injective, and by Exercise 7.23 (or Exercise 12.50), pure submodules with finitely-presented quotients are direct summands.

Fix a finitely generated  $R$ -module  $Z$ . To show that  $Z \otimes_R p$  is injective, we may localize at a maximal ideal and assume that  $(R, \mathfrak{m})$  is local. Suppose  $c \in Z \otimes N$  is a non-zero element of the kernel of  $Z \otimes_R p$ . Take  $n$  so large that  $c \notin \mathfrak{m}^n(Z \otimes_R N) = \mathfrak{m}^n Z \otimes_R N$ . Tensoring further with  $R/\mathfrak{m}^n$  gives the right-exact sequence

$$(Z/\mathfrak{m}^n Z) \otimes_R N \xrightarrow{\bar{p}} (Z/\mathfrak{m}^n Z) \otimes_R X_\alpha \longrightarrow (Z/\mathfrak{m}^n Z) \otimes_R M \longrightarrow 0$$

of finite length  $R$ -modules. Counting lengths shows that  $\bar{p}$  is injective, contradicting the presence of the nonzero element  $\bar{c}$  in the kernel.  $\square$

Let

$$\alpha: \quad 0 \longrightarrow N \longrightarrow X_\alpha \longrightarrow M \longrightarrow 0$$

$$\beta: \quad 0 \longrightarrow N \longrightarrow X_\beta \longrightarrow M \longrightarrow 0$$

be two extensions of  $N$  by  $M$ , with  $X_\alpha \cong X_\beta$ . As mentioned above,  $\alpha$  and  $\beta$  need not represent the same element of  $\text{Ext}_R^1(M, N)$ . In the rest of this section we describe a result of Striuli [Str05] giving a partial result in that direction.

**7.2 Remark.** We recall briefly a few more details of the Yoneda correspondence for  $\text{Ext}^1$ . First, recall that if  $\alpha \in \text{Ext}_R^1(M, N)$  is represented by the short exact sequence

$$\alpha: \quad 0 \longrightarrow N \longrightarrow X_\alpha \longrightarrow M \longrightarrow 0,$$

then for  $r \in R$ , the product  $r\alpha$  can be computed via either a pullback or a pushout. Precisely,  $r\alpha$  is represented either by the top row of the diagram

$$\begin{array}{ccccccccc} r\alpha: & 0 & \longrightarrow & N & \longrightarrow & P & \longrightarrow & M & \longrightarrow & 0 \\ & & & \parallel & & \downarrow & & \downarrow r & & \\ \alpha: & 0 & \longrightarrow & N & \xrightarrow{p} & X & \xrightarrow{q} & M & \longrightarrow & 0 \end{array}$$

or the bottom row of the diagram

$$\begin{array}{ccccccccc} \alpha: & 0 & \longrightarrow & N & \xrightarrow{p} & X & \xrightarrow{q} & M & \longrightarrow & 0 \\ & & & \downarrow r & & \downarrow & & \parallel & & \\ r\alpha: & 0 & \longrightarrow & N & \longrightarrow & Q & \longrightarrow & M & \longrightarrow & 0 \end{array}$$

where

$$P = \{(x, m) \in X \oplus M \mid q(x) = rm\}$$

and

$$Q = X \oplus N / \langle (p(n), -rn) \mid n \in N \rangle.$$

More generally, the same sorts of diagrams define actions of  $\text{End}_R(M)$  and  $\text{End}_R(N)$  on  $\text{Ext}_R^1(M, N)$ , on the right and left respectively, replacing  $r$  by an endomorphism of the appropriate module.

Pullbacks and pushouts also define the connecting homomorphisms  $\delta$  in the long exact sequences of  $\text{Ext}$ . If  $\alpha \in \text{Ext}_R^1(M, N)$  is as above, then for an  $R$ -module  $Z$  the long exact sequence looks like

$$\cdots \longrightarrow \text{Hom}_R(Z, X) \xrightarrow{q^*} \text{Hom}_R(Z, M) \xrightarrow{\delta} \text{Ext}_R^1(Z, N) \longrightarrow \cdots.$$

The image of a homomorphism  $g: Z \rightarrow M$  in  $\text{Ext}_R^1(M, N)$  is the top row of the pullback diagram below.

$$\begin{array}{ccccccccc} 0 & \longrightarrow & N & \longrightarrow & U & \longrightarrow & Z & \longrightarrow & 0 \\ & & \parallel & & \downarrow & & \downarrow g & & \\ 0 & \longrightarrow & N & \xrightarrow{p} & X & \xrightarrow{q} & M & \longrightarrow & 0 \end{array}$$

In particular, when  $Z = M$  we find that  $\delta(1_M) = \alpha$ . Similar considerations apply for the long exact sequence attached to  $\text{Hom}_R(-, Z)$ .

Here is the result that will occupy the rest of the section. In fact Striuli's result holds for arbitrary Noetherian rings; we leave the straightforward extension to the interested reader.

**7.3 Theorem (Striuli).** *Let  $R$  be a local ring. Let*

$$\begin{array}{l} \alpha: \quad 0 \longrightarrow N \longrightarrow X_\alpha \longrightarrow M \longrightarrow 0 \\ \beta: \quad 0 \longrightarrow N \longrightarrow X_\beta \longrightarrow M \longrightarrow 0 \end{array}$$

be two short exact sequences of finitely generated  $R$ -modules. Suppose that  $X_\alpha \cong X_\beta$  and that  $\beta \in I \text{Ext}_R^1(M, N)$  for some ideal  $I$  of  $R$ . Then the complex  $\alpha \otimes_R R/I$  is a split exact sequence.

We need one preliminary result.

**7.4 Proposition.** *Let  $(R, \mathfrak{m})$  be a local ring and  $I$  an ideal of  $R$ . Let*

$$\alpha: \quad 0 \longrightarrow N \xrightarrow{p} X_\alpha \xrightarrow{q} M \longrightarrow 0$$

be a short exact sequence of finitely generated  $R$ -modules, and denote by  $\bar{\alpha} = \alpha \otimes_R R/I$  the complex

$$\bar{\alpha}: \quad 0 \longrightarrow N/IN \xrightarrow{\bar{p}} X_\alpha/IX_\alpha \xrightarrow{\bar{q}} M/IM \longrightarrow 0.$$

If  $\alpha \in I \text{Ext}_R^1(M, N)$ , then  $\bar{\alpha}$  is a split exact sequence.

*Proof.* By Miyata's Theorem 7.1 it is enough to show that  $X_\alpha/IX_\alpha \cong M/IM \oplus N/IN$ . Let

$$\xi: \quad 0 \longrightarrow Z \xrightarrow{i} F_0 \xrightarrow{d_0} M \longrightarrow 0$$

be the beginning of a minimal resolution of  $M$  over  $R$ , so that  $Z = \text{syz}_1^R(M)$  is the first syzygy of  $M$ . Then applying  $\text{Hom}_R(-, N)$  gives a surjection  $\text{Hom}_R(Z, N) \longrightarrow \text{Ext}_R^1(M, N)$ . In particular  $I \text{Hom}_R(Z, N)$  maps onto  $I \text{Ext}_R^1(M, N)$ , so there exists  $\varphi \in I \text{Hom}_R(Z, N)$  such that  $\alpha$  is obtained from the pushout diagram below.

$$\begin{array}{ccccccc} \xi: & 0 & \longrightarrow & Z & \xrightarrow{i} & F_0 & \xrightarrow{d_0} & M & \longrightarrow & 0 \\ & & & \varphi \downarrow & & \psi \downarrow & & \parallel & & \\ \alpha: & 0 & \longrightarrow & N & \xrightarrow{p} & X_\alpha & \xrightarrow{q} & M & \longrightarrow & 0 \end{array}$$

In particular, we have  $\varphi(Z) \subseteq IN$ . The pushout diagram also induces an exact sequence

$$v: \quad 0 \longrightarrow Z \xrightarrow{\begin{bmatrix} i \\ -\varphi \end{bmatrix}} F_0 \oplus N \xrightarrow{[\psi \ p]} X_\alpha \longrightarrow 0.$$

Let  $L$  be an arbitrary  $R/I$ -module of finite length, and tensor both  $\xi$  and  $v$  with  $L$ :

$$\begin{aligned} Z \otimes_R L &\xrightarrow{i \otimes 1_L} F_0 \otimes_R L \xrightarrow{d_0 \otimes 1_L} M \otimes_R L \longrightarrow 0 \\ Z \otimes_R L &\xrightarrow{\begin{bmatrix} i \otimes 1_L \\ -\varphi \otimes 1_L \end{bmatrix}} (F_0 \otimes_R L) \oplus (N \otimes_R L) \xrightarrow{\begin{bmatrix} \psi \otimes 1_L \\ p \otimes 1_L \end{bmatrix}^T} X_\alpha \otimes_R L \longrightarrow 0. \end{aligned}$$

Since  $\varphi(Z) \subseteq IN$  and  $IL = 0$ , the image of  $-\varphi \otimes 1_L$  is zero in  $N \otimes_R L$ . Denoting the image of  $i \otimes 1$  by  $K$ , we get exact sequences

$$\begin{aligned} 0 &\longrightarrow K \longrightarrow F_0 \otimes_R L \longrightarrow M \otimes_R L \longrightarrow 0 \\ 0 &\longrightarrow K \longrightarrow (F_0 \otimes_R L) \oplus (N \otimes_R L) \longrightarrow X_\alpha \otimes_R L \longrightarrow 0. \end{aligned}$$

Counting lengths (over either  $R$  or  $R/I$ , equally) now gives

$$\ell(X_\alpha \otimes_R L) = \ell(M \otimes_R L) + \ell(N \otimes_R L).$$

In particular, since  $L$  is an  $R/I$ -module, we have

$$\ell(X_\alpha/IX_\alpha \otimes_{R/I} L) = \ell(M/IM \otimes_{R/I} L) + \ell(N/IN \otimes_{R/I} L).$$

Exercise 7.25 now applies, as  $L$  was arbitrary, to give  $X_\alpha/IX_\alpha \cong M/IM \oplus N/IN$ .  $\square$

*Proof of Theorem 7.3.* Since  $\beta \in I\text{Ext}_R^1(M, N)$ , Proposition 7.4 implies that  $X_\beta/IX_\beta \cong M/IM \oplus N/IN$  and hence  $X_\alpha/IX_\alpha \cong M/IM \oplus N/IN$ . Applying Miyata's Theorem 7.1, we have that  $\alpha \otimes_R R/I$  is split exact.  $\square$

Here is an amusing consequence.

**7.5 Corollary.** *Let  $(R, \mathfrak{m})$  be a local ring and  $M$  a non-free finitely generated module. Let  $\alpha$  be the short exact sequence*

$$\alpha: \quad 0 \longrightarrow M_1 \longrightarrow F \longrightarrow M \longrightarrow 0,$$

where  $F$  is a finitely generated free module and  $M_1 \subseteq \mathfrak{m}F$ . Then  $\alpha$  is a part of a minimal generating set of  $\text{Ext}_R^1(M, M_1)$ .

*Proof.* If  $\alpha \in \mathfrak{m} \text{Ext}_R^1(M, M_1)$ , then  $\bar{\alpha} = \alpha \otimes R/\mathfrak{m}$  is split exact. But since  $M_1 \subseteq \mathfrak{m}F$ , the image of  $M_1 \otimes R/\mathfrak{m}$  is zero, a contradiction.  $\square$

**7.6 Example.** The converse of Proposition 7.4 fails. Consider the one-dimensional  $(A_2)$  singularity  $R = k[[t^2, t^3]]$ . Since  $R$  is Gorenstein,  $\text{Ext}_R^1(k, R) \cong k$ , and so every nonzero element of  $\text{Ext}_R^1(k, R)$  is part of a basis. Define  $\alpha$  to be the bottom row of the pushout diagram

$$\begin{array}{ccccccc} 0 & \longrightarrow & \mathfrak{m} & \longrightarrow & R & \longrightarrow & k \longrightarrow 0 \\ & & \downarrow \varphi & & \downarrow & & \parallel \\ 0 & \longrightarrow & R & \longrightarrow & X & \longrightarrow & k \longrightarrow 0 \end{array}$$

where  $\varphi$  is defined by  $\varphi(t^2) = t^3$  and  $\varphi(t^3) = t^4$ . Then  $\alpha$  is non-split, since there is no map  $R \rightarrow R$  extending  $\varphi$ , whence  $\alpha \notin \mathfrak{m} \text{Ext}_R^1(k, R)$ . On the other hand,  $\mu(X) = 2$  and hence  $X/\mathfrak{m}X \cong k \oplus k$ . It follows that  $\bar{\alpha}$  is split exact.

These results raise the following question, which will be particularly relevant in Chapter 14.

**7.7 Question.** Let  $(R, \mathfrak{m})$  be a CM local ring and let  $M$  and  $N$  be MCM  $R$ -modules. Take a maximal regular sequence  $\mathbf{x}$  on  $R$ ,  $M$ , and  $N$ , and take  $\alpha \in \text{Ext}_R^1(M, N)$ . Is it true that  $\alpha \in \mathbf{x}\text{Ext}_R^1(M, N)$  if and only if  $\alpha \otimes R/(\mathbf{x})$  is split exact?

## §2 Isolated singularities

Now we come to the first major theorem in the general theory of CM local rings of finite CM type: that they have at most isolated singularities. The result is due originally to Auslander [Aus86a] for complete local rings, though as Yoshino observed, the original proof relies only on the KRS property, hence works equally well for Henselian rings by Theorem 1.8. Auslander’s argument is a tour de force of functorial imagination, and an early vindication of the use of almost split sequences in commutative algebra (cf. Chapter 12). Here we give a simple argument due to Huneke and Leuschke [HL02], valid for all CM local rings, using the results of the previous section.

**7.8 Definition.** Let  $(R, \mathfrak{m})$  be a local ring. We say that  $R$  is, or has, an *isolated singularity* provided  $R_{\mathfrak{p}}$  is a regular local ring for all non-maximal prime ideals  $\mathfrak{p}$ .

Note that we include the case where  $R$  is regular under the definition above. We also say  $R$  has “at most” an isolated singularity to explicitly allow this possibility.

The next lemma is standard, and we leave its proof as an exercise (Exercise 7.27).

**7.9 Lemma.** *Let  $(R, \mathfrak{m})$  be a CM local ring. Then the following conditions are equivalent.*

- (i) *The ring  $R$  has at most an isolated singularity.*
- (ii) *Every MCM  $R$ -module is locally free on the punctured spectrum.*
- (iii) *For all MCM  $R$ -modules  $M$  and  $N$ ,  $\text{Ext}_R^1(M, N)$  has finite length.  $\square$*

**7.10 Lemma.** *Let  $(R, \mathfrak{m})$  be a local ring,  $r \in \mathfrak{m}$ , and*

$$\begin{array}{ccccccc} \alpha: & 0 & \longrightarrow & N & \xrightarrow{i} & X_\alpha & \longrightarrow M \longrightarrow 0 \\ & & & \downarrow r & & \downarrow f & \parallel \\ r\alpha: & 0 & \longrightarrow & N & \xrightarrow{j} & X_{r\alpha} & \longrightarrow M \longrightarrow 0 \end{array}$$

*a commutative diagram of short exact sequences of finitely generated  $R$ -modules. Assume that  $X_\alpha \cong X_{r\alpha}$  (not necessarily via the map  $f$ ). Then  $\alpha \in r \text{Ext}_R^1(M, N)$ .*

Note that the case  $r = 0$  is Miyata's Theorem 7.1.

*Proof.* The pushout diagram gives an exact sequence

$$0 \longrightarrow N \xrightarrow{\begin{bmatrix} r \\ -i \end{bmatrix}} N \oplus X_\alpha \xrightarrow{[j \ f]} X_{r\alpha} \longrightarrow 0.$$

Since  $N \oplus X_\alpha \cong N \oplus X_{r\alpha}$ , Miyata's Theorem 7.1 implies that the sequence splits. In particular, the induced map on  $\text{Ext}$ ,

$$\begin{bmatrix} r \\ -i_* \end{bmatrix} : \text{Ext}_R^1(M, N) \longrightarrow \text{Ext}_R^1(M, N) \oplus \text{Ext}_R^1(M, X_\alpha),$$

is a split injection. Let  $h$  be a right inverse for  $\begin{bmatrix} r \\ -i_* \end{bmatrix}$ .

Now apply  $\text{Hom}_R(M, -)$  to  $\alpha$ , getting an exact sequence

$$\cdots \longrightarrow \text{Hom}_R(M, M) \xrightarrow{\delta} \text{Ext}_R^1(M, N) \xrightarrow{i_*} \text{Ext}_R^1(M, X_\alpha) \longrightarrow \cdots .$$

The connecting homomorphism  $\delta$  takes  $1_M$  to  $\alpha$ , so  $i_*(\alpha) = 0$ . Thus

$$\alpha = h(r\alpha, 0) = rh(\alpha, 0) \in r \text{Ext}_R^1(M, N). \quad \square$$

**7.11 Theorem.** *Let  $(R, \mathfrak{m})$  be local and  $M, N$  finitely generated  $R$ -modules. Suppose there are only finitely many isomorphism classes of modules  $X$  for which there exists a short exact sequence*

$$0 \longrightarrow N \longrightarrow X \longrightarrow M \longrightarrow 0.$$

Then  $\text{Ext}_R^1(M, N)$  has finite length.

*Proof.* Let  $\alpha \in \text{Ext}_R^1(M, N)$ , and let  $r \in \mathfrak{m}$ . By Exercise 7.26, it will suffice to prove that  $r^n \alpha = 0$  for  $n \gg 0$ . For any integer  $n \geq 0$ , we consider a representative for  $r^n \alpha$ , namely

$$r^n \alpha: \quad 0 \longrightarrow N \longrightarrow X_n \longrightarrow M \longrightarrow 0.$$

Since there are only finitely many such isomorphism classes of  $X_n$ , there exists an infinite sequence  $n_1 < n_2 < \cdots$  such that  $X_{n_i} \cong X_{n_j}$  for every  $i, j$ . Set  $\beta = r^{n_1} \alpha$ , and let  $i > 1$ . Note that  $r^{n_i} \alpha = r^{n_i - n_1} \beta$ . Hence we get the commutative diagram

$$\begin{array}{ccccccc} \beta: & 0 & \longrightarrow & N & \longrightarrow & X_{n_1} & \longrightarrow & M & \longrightarrow & 0 \\ & & & \downarrow r^{n_i - n_1} & & \downarrow & & \parallel & & \\ r^{n_i - n_1} \beta: & 0 & \longrightarrow & N & \longrightarrow & X_{n_i} & \longrightarrow & M & \longrightarrow & 0 \end{array}$$

for each  $i$ . By Lemma 7.10,  $X_{n_1} \cong X_{n_i}$  implies  $\beta \in r^{n_i - n_1} \text{Ext}_R^1(M, N)$  for every  $i$ . This implies  $\beta \in \mathfrak{m}^t \text{Ext}_R^1(M, N)$  for every  $t \geq 1$ , whence, by the Krull Intersection Theorem,  $\beta = 0$ .  $\square$

If  $R$  has finite CM type, then for all MCM modules  $M$  and  $N$ , there exist only finitely many MCM modules  $X$  generated by at most  $\mu_R(M) + \mu_R(N)$  elements, thus finitely many potential middle terms for short exact sequences. Thus we obtain Auslander's theorem:

**7.12 Theorem** (Auslander). *Let  $(R, \mathfrak{m})$  be a CM ring with finite CM type. Then  $R$  has at most an isolated singularity.*

**7.13 Remark.** A non-commutative version of Theorem 7.12 is easy to state, and the same proof applies. This was Auslander's original context [Aus86a]. Specifically, Auslander considers the following situation: Let  $T$  be a complete regular local ring and let  $\Lambda$  be a (possibly non-commutative)  $T$ -algebra which is a finitely generated free  $T$ -module. Say that  $\Lambda$  is *nonsingular* if  $\text{gldim } \Lambda = \dim T$ , and that  $\Lambda$  has *finite representation type* if there are only finitely many isomorphism classes of indecomposable finitely generated (left)  $\Lambda$ -modules that are free as  $T$ -modules. If  $\Lambda$  has finite representation type, then  $\Lambda_{\mathfrak{p}}$  is nonsingular for all non-maximal primes  $\mathfrak{p}$  of  $T$ .

We mention here a few further applications of Theorem 7.11, all based on the same observation. Suppose that  $R$  is a CM local ring and  $M$  is a MCM  $R$ -module such that there are only finitely many non-isomorphic MCM modules of multiplicity less than or equal to  $\mu_R(M) \cdot e(R)$ ; then  $M$  is locally free on the punctured spectrum. This follows immediately from Theorem 7.12 upon taking  $N$  to be the first syzygy of  $M$  in a minimal free

resolution. If in addition  $R$  is a domain, then the criterion simplifies to the existence of only finitely many MCM modules of rank at most  $\mu_R(M)$ .

Obvious candidates for  $M$  are the canonical module  $\omega$ , the conormal  $I/I^2$  of a regular presentation  $R = A/I$ , and the module of Kähler differentials  $\Omega_{R/k}^1$  if  $R$  is essentially of finite type over a field  $k$ . Since the freeness of these modules implies that  $R$  is Gorenstein, resp. complete intersection [Mat89, 19.9], resp. regular [Kun86, Theorem 7.2], we obtain the following corollaries.

**7.14 Corollary.** *Let  $(R, \mathfrak{m})$  be a CM local ring with canonical module  $\omega$ . If  $R$  has only finitely many non-isomorphic MCM modules of multiplicity up to  $r(R)e(R)$ , where  $r(R) = \dim_k \text{Ext}_R^{\dim R}(k, R)$  denotes the Cohen-Macaulay type of  $R$ , then  $R$  is Gorenstein on the punctured spectrum.*

**7.15 Corollary.** *Let  $(A, \mathfrak{n})$  be a regular local ring, and suppose  $I \subseteq \mathfrak{n}^2$  is an ideal such that  $R = A/I$  is CM. Assume that  $I/I^2$  is a MCM  $R$ -module. If  $R$  has only finitely many non-isomorphic MCM modules of multiplicity at most  $\mu_A(I) \cdot e(R)$ , then  $R$  is complete intersection on the punctured spectrum.*

**7.16 Corollary.** *Let  $k$  be a field of characteristic zero, and let  $R$  be a  $k$ -algebra essentially of finite type. Let  $\Omega_{R/k}^1$  be the module of Kähler differentials of  $R$  over  $k$ . Assume that  $\Omega$  is a MCM  $R$ -module. If  $R$  has only finitely many non-isomorphic MCM modules of multiplicity up to  $\text{embdim}(R) \cdot e(R)$ , then  $R$  has at most an isolated singularity.*

The second corollary naturally raises the question of when  $I/I^2$  is a MCM  $A/I$ -module for an ideal  $I$  in a regular local ring  $A$ . Herzog [Her78a]

showed that this is the case if  $A/I$  is Gorenstein and  $I$  has height three; see [HU89] and [Buc81, 6.2.10] for some further results in this direction.

### §3 Classification of two-dimensional CM rings of finite CM type

Our aim in this section is to prove a converse to Herzog's Theorem 6.3, which states that rings of invariants in dimension two have finite CM type. The result, due to Auslander and Esnault, is that if a complete local ring  $R$  of dimension two, with a coefficient field  $k$  of characteristic zero, has finite CM type, then  $R \cong k[[u, v]]^G$  for some finite group  $G \subseteq \mathrm{GL}(n, k)$ .

Auslander's proof relies on a deep topological result of Mumford [Mum61], [Hir95b]. We give Mumford's theorem below, followed by the interpretation and more general statement in commutative algebra due to Flenner [Fle75], see also [CS93].

**7.17 Theorem** (Mumford). *Let  $V$  be a normal complex space of dimension 2 and  $x \in V$  a point. Then the following properties hold.*

- (i) *The local fundamental group  $\pi(V, x)$  is finitely generated.*
- (ii) *If the local homology group  $H_1(V, x)$  vanishes, then  $\pi(V, x)$  is isomorphic to the fundamental group of a valued tree with negative-definite intersection matrix.*
- (iii) *If  $\pi(V, x) = \{1\}$  is trivial, then  $x$  is a regular point.*

To translate Mumford's result into commutative algebra, we recall the definition of the *étale fundamental group*, also called the algebraic fundamental group. See [Mil08] for more details. (We will not attempt maximal generality in this brief sketch; in particular, we will ignore the need to choose a base point.) For a connected normal scheme  $X$ , the étale fundamental group  $\pi_1^{et}(X)$  classifies the finite étale coverings of  $X$  in a manner analogous to the usual fundamental group classifying the covering spaces of a topological space.

The construction of  $\pi_1^{et}$  is clearest when  $X = \text{Spec} A$  for a normal domain  $A$ . Let  $K$  be the quotient field of  $A$ , and fix an algebraic closure  $\Omega$  of  $K$ . Then  $\pi_1^{et}(X) \cong \text{Gal}(L/K)$ , where  $L$  is the union of all the finite separable field extensions  $K'$  of  $K$  contained in  $\Omega$ , and such that the integral closure of  $A$  in  $K'$  is étale over  $A$ . There is a Galois correspondence between subgroups  $H \subseteq \pi_1^{et}(X)$  of finite index and finite étale covers  $A \rightarrow B$  of  $A$ . In particular,  $\pi_1^{et}(X) = 0$  if and only if  $A$  has no non-trivial finite étale covers.

With some extra work, the étale fundamental group can be defined for arbitrary schemes  $X$ . In particular, one may take  $X$  to be the punctured spectrum  $\text{Spec}^\circ A = \text{Spec} A \setminus \{\mathfrak{m}\}$  of a local ring  $(A, \mathfrak{m})$ . We say that the local ring  $(A, \mathfrak{m})$  is *pure* if the induced morphism of étale fundamental groups  $\pi_1^{et}(\text{Spec}^\circ A) \rightarrow \pi_1^{et}(\text{Spec} A)$  is an isomorphism. (Unfortunately this usage of the word “pure” has nothing to do with the usage of the same word earlier in this chapter.) The point is the surjectivity:  $A$  is pure if and only if every étale cover of the punctured spectrum extends to an étale cover of the whole spectrum.

**7.18 Theorem** (Flenner). *Let  $(A, \mathfrak{m}, k)$  be an excellent Henselian local nor-*

mal domain of dimension two. Assume that  $\text{char } k = 0$ . Consider the following conditions.

(i)  $\pi_1^{et}(\text{Spec}^\circ A) = 0$ ;

(ii)  $A$  is pure;

(iii)  $A$  is a regular local ring.

Then (a)  $\implies$  (b)  $\iff$  (c), and the three conditions are equivalent if  $k$  is algebraically closed.

The implication “ $A$  regular  $\implies A$  pure” is a restatement of the theorem on the purity of the branch locus (Theorem B.12). The content of the theorem of Mumford and Flenner is in the other implications, in particular, a converse to purity of the branch locus.

Now we come to Auslander’s characterization of the two-dimensional complete local rings of finite CM type in characteristic zero.

**7.19 Theorem.** *Let  $R$  be a complete CM local ring of dimension two with a coefficient field  $k$ . Assume that  $k$  has characteristic zero. If  $R$  has finite CM type, then there exists a power series ring  $S = k[[u, v]]$  and a finite group  $G$  acting on  $S$  by linear changes of variables such that  $R \cong S^G$ .*

*Proof.* First, notice that by Theorem 7.12  $R$  is regular in codimension one, whence a normal domain.

Let  $K$  be the quotient field of the normal domain  $R$ , and fix an algebraic closure  $\Omega$ . Consider the family of all finite field extensions  $K'$  of  $K$ , contained in  $\Omega$ , and such that the integral closure of  $R$  in  $K'$  is unramified

in codimension one over  $R$ . Let  $L$  be the field generated by all these  $K'$ , and let  $S$  be the integral closure of  $R$  in  $L$ .

We will show that  $L$  is a finite Galois extension of  $K$ , so that in particular  $S$  is a module-finite  $R$ -algebra. Observe that if we show this, then by construction  $S$  has no module-finite ring extensions which are unramified in codimension one; indeed, any such ring extension would also be module-finite and unramified in codimension one over  $R$ . (See Appendix B.) In other words, we will have  $\pi_1^{et}(\text{Spec} S \setminus \{\mathfrak{m}_S\}) = 0$  and it will follow that  $S$  is a regular local ring, hence  $S \cong k[[u, v]]$ .

To show that  $L/K$  is a finite Galois extension, assume that there is an infinite ascending chain

$$K \subsetneq L_1 \subsetneq L_2 \subsetneq \cdots \subsetneq L$$

of finite Galois extensions of  $K$  inside  $L$ . Let  $S_i$  be the integral closure of  $R$  in  $L_i$ . Then we have a corresponding infinite ascending chain

$$R \subsetneq S_1 \subsetneq S_2 \subsetneq \cdots \subsetneq S$$

of module-finite ring extensions. Each  $S_i$  is a normal domain, so in particular a reflexive  $R$ -module. By Exercise 4.30, the  $S_i$  are pairwise non-isomorphic as  $R$ -modules, contradicting the assumption that  $R$  has finite CM type. Thus  $L/K$  is finite, and it's easy to see it is a Galois extension. Let  $G$  be the Galois group of  $L$  over  $K$ . Then  $G$  acts on  $S$  with fixed ring  $R$ , and the argument of Lemma 5.3 allows us to assume the action is linear.  $\square$

Theorem 7.19 is false in positive characteristic. Artin [Art77] has given counterexamples to Mumford's characterization of smoothness in characteristic  $p > 0$ ; the simplest is the  $(A_{p-1})$  singularity  $x^2 + y^p + z^2 = 0$ , which

has trivial étale fundamental group, and which has finite CM type by Theorem 6.22. Thus in particular  $k[[x, y, z]]/(x^2 + y^p + z^2)$  is not a ring of invariants when  $k$  has characteristic  $p$ .

Among other things, Theorem 7.19 implies that the two-dimensional CM local rings of finite CM type with residue field  $\mathbb{C}$  have *rational singularities* (see Definition 6.30). This suggests the following conjecture.

**7.20 Conjecture.** *Let  $(R, \mathfrak{m})$  be a CM local ring of dimension at least two. Assume that  $R$  has finite CM type. Then  $R$  has rational singularities.*

The assumption  $\dim R \geq 2$  is necessary to allow for the existence of non-normal, that is, non-regular, one-dimensional rings of finite CM type.

To add some evidence for this conjecture, we recall that by Mumford [Mum61] (in characteristic zero) and Lipman [Lip69] (in characteristic  $p > 0$ ), a normal surface singularity  $X = \operatorname{Spec} R$  has a rational singularity if and only if there are only finitely many rank one MCM  $R$ -modules up to isomorphism.

Here is a weaker version of Conjecture 7.20.

**7.21 Conjecture.** *Let  $(R, \mathfrak{m})$  be a CM local ring of dimension at least two. If  $R$  has finite CM type, then  $R$  has minimal multiplicity, that is,*

$$e(R) = \mu_R(\mathfrak{m}) - \dim R + 1.$$

Recall that rational singularity implies minimal multiplicity, Corollary 6.34. We will prove Conjecture 7.21 for hypersurfaces in Chapter 9, §3, and in fact Conjecture 7.20 for the hypersurface case will follow from the classification in Chapter 9.

## §4 Exercises

**7.22 Exercise.** Prove that the  $p - 1$  non-zero elements of  $\text{Ext}_{\mathbb{Z}}^1(\mathbb{Z}/p\mathbb{Z}, \mathbb{Z}/p\mathbb{Z})$  all have isomorphic middle terms. Find an example of abelian groups  $A$  and  $B$  and two elements of  $\text{Ext}_{\mathbb{Z}}^1(A, B)$  with isomorphic middle terms but different annihilators. (See [Str05] for one example, due to G. Caviglia.)

**7.23 Exercise.** Let  $N \subset M$  be modules over a commutative ring  $R$ . Prove that  $N$  is a pure submodule of  $M$  if and only if the following condition is satisfied: Whenever  $x_1, \dots, x_t$  is a sequence of elements in  $N$ , and  $x_i = \sum_{j=1}^s r_{ij} m_j$  for some  $r_{ij} \in R$  and  $m_j \in M$ , there exist  $y_1, \dots, y_s \in N$  such that  $x_i = \sum_{j=1}^s r_{ij} y_j$  for  $i = 1, \dots, t$ . Conclude that if  $M/N$  is finitely presented and  $N \subset M$  is pure, then the inclusion of  $N$  into  $M$  splits. (See also Exercise 12.50.)

**7.24 Exercise.** Let  $R$  be a commutative Artinian ring and let  $M, N$  be two finitely generated  $R$ -modules. Prove that  $M \cong N$  if and only if  $\ell(\text{Hom}_R(M, X)) = \ell(\text{Hom}_R(N, X))$  for every finitely generated  $R$ -module  $X$ . (Hint: It suffices by induction on  $\ell(\text{Hom}_R(N, N))$  to show that  $M$  and  $N$  have a non-zero direct summand in common. To show this, take generators  $f_1, \dots, f_r$  for  $\text{Hom}_R(M, N)$  to define a homomorphism  $F: M^{(r)} \rightarrow N$ , and show that  $F$  splits.) See [Bon89].

**7.25 Exercise.** Prove that the following are equivalent for finitely generated modules  $M$  and  $N$  over a local ring  $(R, \mathfrak{m})$ .

- (i)  $M \cong N$ ;
- (ii)  $\ell(\text{Hom}_R(M, L)) = \ell(\text{Hom}_R(N, L))$  for every  $R$ -module  $L$  of finite length;

(iii)  $\ell(M \otimes_R L) = \ell(N \otimes_R L)$  for every  $R$ -module  $L$  of finite length.

(Hint: Use Matlis duality for (ii)  $\implies$  (iii). Assuming (ii), reduce modulo  $\mathfrak{m}^n$  and conclude from Exercise 7.24 that  $M/\mathfrak{m}^n M \cong N/\mathfrak{m}^n N$  for every  $n$ , then use Corollary 1.14.)

**7.26 Exercise.** Let  $(R, \mathfrak{m})$  be local, and let  $M$  be a finitely generated  $R$ -module. Show that  $M$  has finite length if and only if for all  $r \in \mathfrak{m}$  and for all  $x \in M$ , there exists an integer  $n$  such that  $r^n x = 0$ .

**7.27 Exercise.** Prove a slightly more general version of Lemma 7.9: if  $R$  is a local ring, then for the conditions below we have (i)  $\implies$  (ii)  $\implies$  (iii), and (iii)  $\implies$  (i) if  $R$  is CM.

(i) The ring  $R$  has at most an isolated singularity.

(ii) Every MCM  $R$ -module is locally free on the punctured spectrum.

(iii) For all MCM  $R$ -modules  $M$  and  $N$ ,  $\text{Ext}_R^1(M, N)$  has finite length.

# 8

## *The double branched cover*

In this chapter we introduce two key tools in the representation theory of hypersurface rings: matrix factorizations and the double branched cover. We fix the following notation for the entire chapter.

**8.1 Conventions.** Let  $(S, \mathfrak{n}, k)$  be a regular local ring and let  $f$  be a non-zero element of  $\mathfrak{n}^2$ . Put  $R = S/(f)$  and  $\mathfrak{m} = \mathfrak{n}/(f)$ . We let  $d = \dim(R) = \dim(S) - 1$ .

### §1 Matrix factorizations

With the notation of 8.1, suppose  $M$  is a MCM  $R$ -module. Then  $M$  has depth  $d$  when viewed as an  $R$ -module or as an  $S$ -module. By the Auslander-Buchsbaum formula,  $M$  has projective dimension 1 over  $S$ . Therefore the minimal free resolution of  $M$  as an  $S$ -module is of the form

$$(8.1.1) \quad 0 \longrightarrow G \xrightarrow{\varphi} F \longrightarrow M \longrightarrow 0,$$

where  $G$  and  $F$  are finitely generated free  $S$ -modules. Since  $f \cdot M = 0$ ,  $M$  is a torsion  $S$ -module, so  $\text{rank}_S G = \text{rank}_S F$ .

For any  $x \in F$ , the image of  $fx$  in  $M$  vanishes, so there is a unique element  $y \in G$  such that  $\varphi(y) = fx$ . Since the element  $y$  is linearly determined by  $x$ , we get a homomorphism  $\psi: F \rightarrow G$  satisfying  $\varphi\psi = f 1_F$ . It follows from the injectivity of the map  $\varphi$  that  $\psi\varphi = f 1_G$  too. This construction motivates the following definition [Eis80].

**8.2 Definition.** Let  $(S, \mathfrak{n}, k)$  be a regular local ring, and let  $f$  be a non-zero element of  $\mathfrak{n}^2$ . A *matrix factorization* of  $f$  is a pair  $(\varphi, \psi)$  of homomorphisms between free  $S$ -modules of the same rank,  $\varphi: G \rightarrow F$  and  $\psi: F \rightarrow G$ , such that

$$\psi\varphi = 1_G \quad \text{and} \quad \varphi\psi = 1_F.$$

Equivalently (after choosing bases),  $\varphi$  and  $\psi$  are square matrices of the same size over  $S$ , say  $n \times n$ , such that

$$\psi\varphi = \varphi\psi = I_n.$$

Let  $(\varphi, \psi)$  be a matrix factorization of  $f$  as in Definition 8.2. Since  $f$  is a non-zerodivisor, it follows that  $\varphi$  and  $\psi$  are injective, and we have short exact sequences

$$(8.2.1) \quad \begin{array}{ccccccc} 0 & \longrightarrow & G & \xrightarrow{\varphi} & F & \longrightarrow & \text{cok } \varphi \longrightarrow 0 \\ 0 & \longrightarrow & F & \xrightarrow{\psi} & G & \longrightarrow & \text{cok } \psi \longrightarrow 0 \end{array}$$

of  $S$ -modules. As  $fF = \varphi\psi(F)$  is contained in the image of  $\varphi$ , the cokernel of  $\varphi$  is annihilated by  $f$ . Similarly,  $f \cdot \text{cok } \psi = 0$ . Thus  $\text{cok } \varphi$  and  $\text{cok } \psi$  are naturally finitely generated modules over  $R = S/(f)$ .

**8.3 Proposition.** *Let  $(S, \mathfrak{n})$  be a regular local ring and let  $f$  be a non-zero element of  $\mathfrak{n}^2$ .*

- (i) *For every MCM  $R$ -module, there is a matrix factorization  $(\varphi, \psi)$  of  $f$  with  $\text{cok } \varphi \cong M$ .*
- (ii) *If  $(\varphi, \psi)$  is a matrix factorization of  $f$ , then  $\text{cok } \varphi$  and  $\text{cok } \psi$  are MCM  $R$ -modules.*

*Proof.* Only the second statement needs verification. The exact sequences (8.2.1) and the fact that  $f \cdot \text{cok } \varphi = 0 = f \cdot \text{cok } \psi$  imply that the cokernels have projective dimension one over  $S$ . By the Auslander-Buchsbaum formula, they have depth equal to  $\dim S - 1 = \dim R$  and therefore are MCM  $R$ -modules.  $\square$

**8.4 Notation.** When we wish to emphasize the provenance of a presentation matrix  $\varphi$  as half of a matrix factorization  $(\varphi, \psi)$ , we write  $\text{cok}(\varphi, \psi)$  in place of  $\text{cok } \varphi$ . We also write  $(\varphi: G \rightarrow F, \psi: F \rightarrow G)$  to include the free  $S$ -module  $G$  and  $F$  in the notation.

There are two distinguished *trivial* matrix factorizations of any element  $f$ , namely  $(f, 1)$  and  $(1, f)$ . Note that  $\text{cok}(1, f) = 0$ , while  $\text{cok}(f, 1) \cong R$ .

**8.5 Definition.** Let  $(\varphi: G \rightarrow F, \psi: F \rightarrow G)$  and  $(\varphi': G' \rightarrow F', \psi': F' \rightarrow G')$  be matrix factorizations of  $f \in S$ . A *homomorphism of matrix factorizations* between  $(\varphi, \psi)$  and  $(\varphi', \psi')$  is a pair of  $S$ -module homomorphisms  $\alpha: F \rightarrow F'$  and  $\beta: G \rightarrow G'$  rendering the diagram

$$(8.5.1) \quad \begin{array}{ccccc} F & \xrightarrow{\psi} & G & \xrightarrow{\varphi} & G \\ \alpha \downarrow & & \downarrow \beta & & \downarrow \alpha \\ F' & \xrightarrow{\psi'} & G' & \xrightarrow{\varphi'} & F' \end{array}$$

commutative. (In fact, commutativity of just one of the squares is sufficient; see Exercise 8.31.)

A homomorphism of matrix factorizations  $(\alpha, \beta): (\varphi, \psi) \rightarrow (\varphi', \psi')$  induces a homomorphism of  $R$ -modules  $\text{cok}(\varphi, \psi) \rightarrow \text{cok}(\varphi', \psi')$ , which we denote  $\text{cok}(\alpha, \beta)$ . Conversely, every  $S$ -module homomorphism  $\text{cok}(\varphi, \psi) \rightarrow$

$\text{cok}(\varphi', \psi')$  lifts to give a commutative diagram

$$\begin{array}{ccccccccc}
 0 & \longrightarrow & G & \xrightarrow{\varphi} & F & \longrightarrow & \text{cok}(\varphi, \psi) & \longrightarrow & 0 \\
 & & \downarrow \beta & & \downarrow \alpha & & \downarrow & & \\
 0 & \longrightarrow & G' & \xrightarrow{\varphi'} & F' & \longrightarrow & \text{cok}(\varphi', \psi') & \longrightarrow & 0
 \end{array}$$

with exact rows, and thus a homomorphism of matrix factorizations.

Two matrix factorizations  $(\varphi, \psi)$  and  $(\varphi', \psi')$  are *equivalent* if there is a homomorphism of matrix factorizations  $(\alpha, \beta): (\varphi, \psi) \rightarrow (\varphi', \psi')$  in which both  $\alpha$  and  $\beta$  are isomorphisms.

Direct sums of matrix factorizations are defined in the natural way:

$$(\varphi, \psi) \oplus (\varphi', \psi') = \left( \left( \begin{array}{c} \varphi \\ \varphi' \end{array} \right), \left( \begin{array}{c} \psi \\ \psi' \end{array} \right) \right).$$

We say that a matrix factorization is *reduced* provided it is not equivalent to a matrix factorizations having a trivial direct summand  $(f, 1)$  or  $(1, f)$ . It's straightforward to see that  $(\varphi, \psi)$  is reduced if and only if all the entries of  $\varphi$  and  $\psi$  are in the maximal ideal of  $S$ . See Exercise 8.32. In particular,  $\varphi$  has no unit entries if and only if  $\text{cok}(\varphi, \psi)$  has no non-zero  $R$ -free direct summands.

With bars denoting reduction modulo  $f$ , a matrix factorization  $(\varphi: G \rightarrow F, \psi: F \rightarrow G)$  induces a complex

$$(8.5.2) \quad \dots \longrightarrow \overline{G} \xrightarrow{\overline{\varphi}} \overline{F} \xrightarrow{\overline{\psi}} \overline{G} \xrightarrow{\overline{\varphi}} \overline{F} \longrightarrow \text{cok}(\varphi, \psi) \longrightarrow 0$$

in which  $\overline{G}$  and  $\overline{F}$  are finitely generated free modules over  $R = S/(f)$ . In fact (Exercise 8.33), this complex is exact, hence is a free resolution of  $\text{cok}(\varphi, \psi)$ . If  $(\varphi, \psi)$  is a reduced matrix factorization, then (8.5.2) is a minimal  $R$ -free resolution of  $\text{cok}(\varphi, \psi)$ .

The reversed pair  $(\psi, \varphi)$  is also a matrix factorization of  $f$ , and the resolution (8.5.2) exhibits  $\text{cok}(\psi, \varphi)$  as a first syzygy of  $\text{cok}(\varphi, \psi)$  and vice versa:

$$(8.5.3) \quad \begin{array}{ccccccc} 0 & \longrightarrow & \text{cok}(\psi, \varphi) & \longrightarrow & \overline{F} & \longrightarrow & \text{cok}(\varphi, \psi) \longrightarrow 0 \\ 0 & \longrightarrow & \text{cok}(\varphi, \psi) & \longrightarrow & \overline{G} & \longrightarrow & \text{cok}(\psi, \varphi) \longrightarrow 0 \end{array}$$

are exact sequences of  $R$ -modules. This gives the first assertion of the next result; we leave the rest, and the proof of the theorem following, as exercises. Recall that an  $R$ -module  $M$  is *stable* provided it does not have a direct summand isomorphic to  $R$ . We remark that a direct sum of two stable modules is again stable, by KRS (or directly, cf. Exercise 8.34).

**8.6 Proposition.** *Keep the notation of 8.1.*

- (i) *Let  $M$  be a MCM  $R$ -module. Then  $M$  has a free resolution which is periodic of period at most two.*
- (ii) *Let  $M$  be a stable MCM  $R$ -module. Then the minimal free resolution of  $M$  is periodic of period at most two.*
- (iii) *Let  $M$  be a MCM  $R$ -module. Then  $\text{syz}_1^R M$  is a stable MCM  $R$ -module. If  $M$  is indecomposable, so is  $\text{syz}_1^R M$ .*
- (iv) *Let  $M$  be a finitely generated  $R$ -module. Then the minimal free resolution of  $M$  is eventually periodic of period at most two. In particular the minimal free resolution of  $M$  is bounded.*
- (v) *Let  $M$  and  $N$  be  $R$ -modules with  $M$  finitely generated. For each  $i \geq \dim R$ , we have  $\text{Ext}_R^i(M, N) \cong \text{Ext}_R^{i+2}(M, N)$  and  $\text{Tor}_i^R(M, N) \cong \text{Tor}_{i+2}^R(M, N)$ .*

In the next chapter we will see a converse to (iii): If every minimal free resolution over a local ring  $R$  is bounded, then (the completion of)  $R$  is a hypersurface ring.

**8.7 Theorem** ([Eis80, Theorem 6.3]). *Keep the notation of 8.1. The association*

$$(\varphi, \psi) \longleftrightarrow \text{cok}(\varphi, \psi)$$

*induces an equivalence of categories between reduced matrix factorizations of  $f$  up to equivalence and of stable MCM  $R$ -modules up to isomorphism. In particular, it gives a bijection between equivalence classes of reduced matrix factorizations and isomorphism classes of stable MCM modules.  $\square$*

**8.8 Remark.** If in addition  $f$  is a prime/irreducible element of  $S$ , so that  $R$  is an integral domain, then from  $\varphi\psi = f \cdot I_n$  it follows that both  $\det \varphi$  and  $\det \psi$  are, up to units, powers of  $f$ . Specifically, we must have  $\det \varphi = u f^k$  and  $\det \psi = u^{-1} f^{n-k}$  for some unit  $u \in S$  and  $k \leq n$ . In this case the  $R$ -module  $\text{cok}(\varphi, \psi)$  has rank  $k$ , while  $\text{cok}(\psi, \varphi)$  has rank  $n - k$ . To see this, localize at the prime ideal  $(f)$ . Then over the discrete valuation ring  $S_{(f)}$ ,  $\varphi$  is equivalent to  $f \cdot 1_k \oplus 1_{n-k}$  and so  $\text{cok} \varphi$  has rank  $k$  over the field  $R_{(f)}$ .

Similar remarks hold when  $f$  is merely reduced, provided we consider  $\text{rank } M$  as the tuple  $(\text{rank}_{R_{\mathfrak{p}}} M_{\mathfrak{p}})$  as  $\mathfrak{p}$  runs over the minimal primes in  $R$ .

**8.9 Remark.** Let  $(\varphi: G \rightarrow F, \psi: F \rightarrow G)$  and  $(\varphi': G' \rightarrow F', \psi': F' \rightarrow G')$  be two matrix factorizations of  $f$ . Put  $M = \text{cok}(\varphi, \psi)$ ,  $N = \text{cok}(\psi, \varphi)$ ,  $M' = \text{cok}(\varphi', \psi')$ , and  $N' = \text{cok}(\psi', \varphi')$ . Then any homomorphism of matrix factorizations  $(\alpha, \beta): (\psi, \varphi) \rightarrow (\psi', \varphi')$  (note the order!) defines a pushout

diagram

$$(8.9.1) \quad \begin{array}{ccccccccc} 0 & \longrightarrow & N & \longrightarrow & \bar{F} & \longrightarrow & M & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \parallel & & \\ 0 & \longrightarrow & M' & \longrightarrow & Q & \longrightarrow & M & \longrightarrow & 0 \end{array}$$

of  $R$ -modules, the bottom row of which is the image of  $\text{cok}(\alpha, \beta)$  under the surjective connecting homomorphism

$$\text{Hom}_R(N, M') \longrightarrow \text{Ext}_R^1(M, M').$$

In particular, every extension of  $M'$  by  $M$  arises in this way.

The middle module  $Q$  is of course MCM as well. Splicing (8.9.1) together with the  $R$ -free resolutions of  $N$  and  $M'$ , we obtain a morphism of exact sequences

$$\begin{array}{ccccccccccc} \dots & \xrightarrow{\bar{\varphi}} & \bar{F} & \xrightarrow{\bar{\psi}} & \bar{G} & \xrightarrow{\bar{\varphi}} & \bar{F} & \longrightarrow & M & \longrightarrow & 0 \\ & & \beta \downarrow & & \downarrow \alpha & & \downarrow & & \parallel & & \\ \dots & \xrightarrow{\bar{\psi}'} & \bar{G}' & \xrightarrow{\bar{\varphi}'} & \bar{F}' & \longrightarrow & Q & \longrightarrow & M & \longrightarrow & 0 \end{array}$$

defined, after the first step, by  $\alpha$  and  $\beta$ . The *mapping cone* of this morphism is thus the exact complex

$$\dots \longrightarrow \bar{F}' \oplus \bar{F} \xrightarrow{\begin{bmatrix} \bar{\psi}' & \beta \\ \bar{\varphi}' & -\bar{\varphi} \end{bmatrix}} \bar{G}' \oplus \bar{G} \xrightarrow{\begin{bmatrix} \bar{\varphi}' & \alpha \\ \bar{\psi}' & -\bar{\psi} \end{bmatrix}} \bar{F}' \oplus \bar{F} \longrightarrow Q \oplus M \longrightarrow M \longrightarrow 0.$$

We may cancel the two occurrences of  $M$  (since the map between them is the identity) and find that

$$Q \cong \text{cok} \left( \begin{pmatrix} \bar{\varphi}' & \alpha \\ & -\bar{\psi}' \end{pmatrix}, \begin{pmatrix} \bar{\psi}' & \beta \\ & -\bar{\varphi}' \end{pmatrix} \right).$$

## §2 The double branched cover

We continue with the notation and conventions established in 8.1 and assume, in addition, that  $S$  is complete. Thus  $(S, \mathfrak{n}, k)$  is a complete regular local ring of dimension  $d + 1$ ,  $0 \neq f \in \mathfrak{n}^2$ , and  $R = S/(f)$ . We will refer to a ring  $R$  of this form as a *complete hypersurface singularity*.

**8.10 Definition.** The *double branched cover* of  $R$  is

$$R^\sharp = S[[z]]/(f + z^2),$$

a complete hypersurface singularity of dimension  $d + 1$ .

**8.11 Warning.** It is important to have a particular defining equation in mind, since different equations defining the same hypersurface  $R$  can lead to non-isomorphic rings  $R^\sharp$ . For example, we have  $\mathbb{R}[[x]]/(x^2) = \mathbb{R}[[x]]/(-x^2)$ , yet  $\mathbb{R}[[x, z]]/(x^2 + z^2) \not\cong \mathbb{R}[[x, z]]/(-x^2 + z^2)$ . (One is a domain; the other is not.) Exercise 8.36 shows that such oddities cannot occur if  $k$  is algebraically closed and of characteristic different from two.

We want to compare the MCM modules over  $R^\sharp$  with those over  $R$ . Observe that we have a surjection  $R^\sharp \rightarrow R$ , killing the class of  $z$ . There is no homomorphism the other way in general. However,  $R^\sharp$  is a finitely generated free  $S$ -module, generated by the images of 1 and  $z$ ; cf. Exercise 8.38.

**8.12 Definition.** Let  $N$  be a MCM  $R^\sharp$ -module. Set

$$N^\flat = N/zN,$$

a MCM  $R$ -module. Contrariwise, let  $M$  be a MCM  $R$ -module. View  $M$  as an  $R^\sharp$ -module via the surjection  $R^\sharp \rightarrow R$ , and set

$$M^\sharp = \text{syz}_1^{R^\sharp} M.$$

Notice that there is no conflict of notation if we view  $R$  as an  $R$ -module and sharp it: Since  $z$  is a non-zerodivisor of  $R^\sharp$  (cf. Exercise 8.37), we have a short exact sequence

$$0 \longrightarrow R^\sharp \xrightarrow{z} R^\sharp \longrightarrow R \longrightarrow 0.$$

Thus  $R^\sharp$  is indeed the first syzygy of  $R$  as an  $R^\sharp$ -module.

**8.13 Notation.** Let  $\varphi: G \rightarrow F$  be a homomorphism of finitely generated free  $S$ -modules, or equivalently a matrix with entries in  $S$ . We use the same symbol  $\varphi$  for the induced homomorphism  $S[[z]] \otimes_S G \rightarrow S[[z]] \otimes_S F$ ; as a matrix, they are identical. In particular we abuse the notation  $1_F$ , using it also for the identity map  $S[[z]] \otimes_S 1_F$ .

Furthermore let  $\tilde{\varphi}: \tilde{G} \rightarrow \tilde{F}$  denote the corresponding homomorphism over  $R^\sharp$ , obtained via the composition of natural homomorphisms  $S \rightarrow S[[z]] \rightarrow S[[z]]/(f + z^2) = R^\sharp$ . Finally, as in §1, we let  $\bar{\varphi}: \bar{G} \rightarrow \bar{F}$  denote the matrix over  $R = S/(f)$  obtained via the natural map  $S \rightarrow R$ . Thus  $\bar{F} = \tilde{F}/z\tilde{F}$ .

**8.14 Lemma.** Let  $(\varphi: G \rightarrow F, \psi: F \rightarrow G)$  be a matrix factorization of  $f$ , let  $M = \text{cok}(\varphi, \psi)$ , and let  $\pi: \tilde{F} \twoheadrightarrow M$  be the composition  $\tilde{F} \twoheadrightarrow \bar{F} \twoheadrightarrow M$ .

(i) There is an exact sequence

$$\tilde{F} \oplus \tilde{G} \xrightarrow{\begin{bmatrix} \tilde{\psi} & -z1_{\tilde{G}} \\ z1_{\tilde{F}} & \tilde{\varphi} \end{bmatrix}} \tilde{G} \oplus \tilde{F} \xrightarrow{[\tilde{\varphi} \ z1_{\tilde{F}}]} \tilde{F} \xrightarrow{\pi} M \longrightarrow 0$$

of  $R^\sharp$ -modules.

(ii) The matrices over  $S[[z]]$

$$\begin{pmatrix} \psi & -z 1_G \\ z 1_F & \varphi \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} \varphi & z 1_F \\ -z 1_G & \psi \end{pmatrix}$$

form a matrix factorization of  $f + z^2$  over  $S[[z]]$ .

(iii) We have

$$M^\sharp \cong \text{cok} \left( \begin{pmatrix} \psi & -z 1_G \\ z 1_F & \varphi \end{pmatrix}, \begin{pmatrix} \varphi & z 1_F \\ -z 1_G & \psi \end{pmatrix} \right)$$

and

$$\text{syz}_1^{R^\sharp}(M^\sharp) \cong M^\sharp.$$

*Proof.* The proof of (ii) amounts to matrix multiplication, and (iii) is an immediate consequence of (i), (ii), and the matrix calculation

$$\begin{pmatrix} & 1 \\ 1 & \end{pmatrix} \begin{pmatrix} \varphi & z 1_F \\ -z 1_G & \psi \end{pmatrix} \begin{pmatrix} 1 & \\ & 1 \end{pmatrix} = \begin{pmatrix} \psi & -z 1_G \\ z 1_F & \varphi \end{pmatrix}$$

over  $S[[z]]$ . It thus suffices to prove (i). First we note that  $z$  is a nonzerodivisor of  $R^\sharp$  (Exercise 8.37). Therefore the columns of the following

commutative diagram are exact.

$$\begin{array}{ccccccc}
 & & 0 & & 0 & & 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 & & \tilde{F} & \xrightarrow{\tilde{\psi}} & \tilde{G} & \xrightarrow{\tilde{\varphi}} & \tilde{F} \\
 & & \downarrow z & & \downarrow z & & \downarrow z \\
 & & \tilde{F} & \xrightarrow{\tilde{\psi}} & \tilde{G} & \xrightarrow{\tilde{\varphi}} & \tilde{F} \\
 & & \downarrow & & \downarrow & & \downarrow \\
 \dots & \xrightarrow{\bar{\varphi}} & \bar{F} & \xrightarrow{\bar{\psi}} & \bar{G} & \xrightarrow{\bar{\varphi}} & \bar{F} \xrightarrow{\pi} M \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 & & 0 & & 0 & & 0
 \end{array}$$

The bottom row is also exact by (8.5.2), but the first two rows aren't even complexes. In fact,

$$(8.14.1) \quad \tilde{\varphi}\tilde{\psi} = -z^2 1_{\tilde{F}} .$$

An easy diagram chase shows that  $\ker \pi = \text{im } \tilde{\varphi} + z\tilde{F} = \text{im } [\tilde{\varphi} \ z 1_{\tilde{F}}]$ . Also,

$$\ker \left[ \begin{array}{cc} \tilde{\varphi} & z 1_{\tilde{F}} \end{array} \right] \cong \text{im} \left[ \begin{array}{cc} \tilde{\psi} & -z 1_{\tilde{G}} \\ z 1_{\tilde{F}} & \tilde{\varphi} \end{array} \right]$$

by (8.14.1). For the opposite inclusion, let  $\begin{bmatrix} x \\ y \end{bmatrix} \in \ker [\tilde{\varphi} \ z 1_{\tilde{F}}]$ , so that  $\tilde{\varphi}(x) = -zy$ . A diagram chase yields elements  $a \in \tilde{F}$  and  $b \in \tilde{G}$  such that  $[\tilde{\psi} \ -z 1_{\tilde{G}}] \begin{bmatrix} a \\ b \end{bmatrix} = x$ . We need to show that  $[z 1_{\tilde{F}} \ \tilde{\varphi}] \begin{bmatrix} a \\ b \end{bmatrix} = y$ . Using (8.14.1), we obtain the equations

$$z(za + \tilde{\varphi}(b)) = -\tilde{\varphi}\tilde{\psi}(a) + z\tilde{\varphi}(b) = -\tilde{\varphi}(\tilde{\psi}(a) - zb) = -\tilde{\varphi}(x) = zy .$$

Cancelling the non-zerodivisor  $z$ , we get the desired result. □

This allows us already to prove one “natural” relation between sharpening and flatting.

**8.15 Proposition.** *Let  $M$  be a MCM  $R$ -module. Then*

$$M^{\sharp\flat} \cong M \oplus \operatorname{syz}_1^R M.$$

*Moreover,  $M$  is a stable  $R$ -module if and only if  $M^{\sharp}$  is a stable  $R^{\sharp}$ -module.*

*Proof.* The  $R$ -module  $M^{\sharp\flat}$  is presented by the matrix factorization  $(\Phi \otimes_{R^{\sharp}} R, \Psi \otimes_{R^{\sharp}} R)$ , where  $(\Phi, \Psi)$  is the matrix factorization for  $M^{\sharp}$  given in Lemma 8.14.

Killing  $z$  in that matrix factorization gives

$$M^{\sharp\flat} \cong \operatorname{cok} \left( \begin{pmatrix} \varphi & \\ & \psi \end{pmatrix}, \begin{pmatrix} \psi & \\ & \varphi \end{pmatrix} \right),$$

as desired. The “Moreover” statement follows from Exercise 8.32, since the entries of the matrix factorization for  $M^{\sharp}$  are those in the matrix factorization for  $M$ , together with  $z$ .  $\square$

Now we turn to the other “natural” relation. Recall that  $R^{\sharp}$  is a free  $S$ -module of rank 2; in particular any MCM  $R^{\sharp}$ -module is a finitely generated free  $S$ -module.

**8.16 Lemma.** *Let  $N$  be a MCM  $R^{\sharp}$ -module. Let  $\varphi: N \rightarrow N$  be an  $S$ -linear homomorphism representing multiplication by  $z$  on  $N$ .*

(i) *The pair  $(\varphi, -\varphi)$  is a matrix factorization of  $f$  with  $\operatorname{cok}(\varphi, -\varphi) \cong N^{\flat}$ .*

(ii) *If  $N$  is stable, then*

$$N^{\flat} \cong \operatorname{syz}_1^R(N^{\flat}),$$

*and hence  $N^{\flat}$  is stable too.*

(iii) Consider  $z 1_N \pm \varphi$  as an endomorphism of  $S[[z]] \otimes_S N$ , a finitely generated free  $S[[z]]$ -module. Then

$$(z 1_N - \varphi, z 1_N + \varphi)$$

is a matrix factorization of  $f + z^2$  with  $\text{cok}(z 1_N - \varphi, z 1_N + \varphi) \cong N$ . If  $N$  is stable, then  $(z 1_N - \varphi, z 1_N + \varphi)$  is a reduced matrix factorization.

*Proof.* On the  $S$ -module  $N$ ,  $-\varphi^2$  corresponds to multiplication by  $-z^2$ . But since  $N$  is an  $R^\sharp$ -module, the action of  $-z^2$  on  $N$  agrees with that of  $f$ . In other words,  $-\varphi^2 = f 1_N$ . Now  $\varphi$  and  $-\varphi$  obviously have isomorphic cokernels, each isomorphic to  $N/zN = N^b$ . Items (i) and (ii) follow. We leave the first assertion of (iii) as Exercise 8.39. For the final sentence, note that if  $z 1_N - \varphi$  contains a unit of  $S[[z]]$ , then  $\varphi$  contains a unit of  $S$  as an entry. But then  $z 1_N + \varphi$  has a unit entry, so that the trivial matrix factorization  $(f + z^2, 1)$  is a direct summand of  $(z 1_N - \varphi, z 1_N + \varphi)$  up to equivalence. This exhibits  $R^\sharp$  as a direct summand of  $N$ , contradicting the stability of  $N$ .  $\square$

**8.17 Proposition.** Let  $N$  be a stable MCM  $R^\sharp$ -module. Assume that  $\text{char } k \neq 2$ . Then

$$N^{b^\sharp} \cong N \oplus \text{syz}_1^{R^\sharp} N.$$

*Proof.* Let  $\varphi: N \rightarrow N$  be the homomorphism of free  $S$ -modules representing multiplication by  $z$  as in Lemma 8.16. Then  $(\varphi, -\varphi)$  is a matrix factorization of  $f$  with  $\text{cok}(\varphi, -\varphi) \cong N^b$  by the Lemma, so that

$$\begin{aligned} N^{b^\sharp} &= \text{syz}_1^{R^\sharp}(N^b) \\ &\cong \text{cok} \left( \left( \begin{array}{cc} -\varphi & -z 1_N \\ z 1_N & \varphi \end{array} \right), \left( \begin{array}{cc} \varphi & z 1_N \\ -z 1_N & -\varphi \end{array} \right) \right) \end{aligned}$$

by (iii) of Lemma 8.14. Noting that  $\frac{1}{2} \in R$  and hence that the matrix  $\begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix}$  is invertible over  $R$ , we pass to an equivalent matrix

$$\begin{bmatrix} z 1_N - \varphi & 0 \\ 0 & z 1_N + \varphi \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} -\varphi & -z 1_N \\ z 1_N & \varphi \end{bmatrix} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix}.$$

Then

$$N^{b\sharp} \cong \text{cok}(z 1_N - \varphi, z 1_N + \varphi) \oplus \text{cok}(z 1_N + \varphi, z 1_N - \varphi) \cong N \oplus \text{syz}_1^{R^\sharp} N$$

by (iii) of Lemma 8.16. □

We now have all the machinery we need to verify that  $R$  has finite CM type if and only if  $R^\sharp$  does. The same arguments take care of the case of *countable* CM type (see Definition 13.1), so in anticipation of Chapter 13 we prove both statements simultaneously.

**8.18 Theorem** (Knörrer). *Let  $(S, \mathfrak{n}, k)$  be a complete regular local ring,  $f$  a non-zero element of  $\mathfrak{n}^2$ , and  $R = S/(f)$ .*

- (i) *If  $R^\sharp$  has finite (respectively countable) CM type, then so has  $R$ .*
- (ii) *If  $R$  has finite (respectively countable) CM type and  $\text{char } k \neq 2$ , then  $R^\sharp$  has finite CM type.*

*Proof.* We will prove (ii), leaving the almost identical proof of (i) to the reader. Let  $\{M_i\}_{i \in I}$  be a representative list of the indecomposable non-free MCM  $R$ -modules, where  $I$  is a finite (respectively countable) index set. Write  $M_i^\sharp = N_{i1} \oplus \cdots \oplus N_{ir_i}$ , where each  $N_{ij}$  is an indecomposable  $R^\sharp$ -module. We will show that every indecomposable non-free MCM  $R^\sharp$ -module is isomorphic to some  $N_{ij}$ .

Let  $N$  be an indecomposable non-free MCM  $R^\sharp$ -module. Then  $N \oplus \text{syz}_1^{R^\sharp}(N)$  is stable, by (v) of Proposition 8.6. It follows from Proposition 8.17 that  $N^\flat$  is a stable  $R$ -module. For, if  $N^\flat \cong X \oplus R$ , then  $N \oplus \text{syz}_1^{R^\sharp}(N) \cong N^\flat \cong X^\sharp \oplus R^\sharp$ , a contradiction.

Write  $N^\flat \cong M_{i_1}^{(e_1)} \oplus \cdots \oplus M_{i_t}^{(e_t)}$ , where the  $e_\ell$  are non-negative integers. Then  $N \oplus \text{syz}_1^{R^\sharp}(N) \cong N^\flat \cong (M_{i_1}^\sharp)^{(e_1)} \oplus \cdots \oplus (M_{i_t}^\sharp)^{(e_t)}$ . By KRS,  $N$  is isomorphic to a direct summand of some  $M_{i_\ell}^\sharp$ , and therefore isomorphic to some  $N_{ij}$ .  $\square$

**8.19 Corollary (ADE Redux).** *Let  $(R, \mathfrak{m}, k)$  be an ADE (or simple) plane curve singularity (cf. Chapter 4, §3) over an algebraically closed field  $k$  of characteristic different from 2, 3 or 5. Then  $R$  has finite CM type.*

*Proof.* The hypersurface  $R^\sharp$  is a complete Kleinian singularity and therefore has finite CM type by Theorem 6.22. By Theorem 8.18,  $R$  has finite CM type.  $\square$

**8.20 Example.** Assume  $k$  is a field with  $\text{char } k \neq 2$ , and let  $n$  and  $d$  be integers with  $n \geq 1$  and  $d \geq 0$ . Put  $R_{n,d} = k[[x, z_1, \dots, z_d]]/(x^{n+1} + z_1^2 + \cdots + z_d^2)$ . The ring  $R_{n,0} = k[[x]]/(x^{n+1})$  obviously has finite CM type (see Theorem 3.2). By applying Theorem 8.18 repeatedly, we see that the  $d$ -dimensional  $(A_n)$ -singularity  $R_{n,d}$  has finite CM type for every  $d$ . Consequently, the ring  $R = k[[x_1, \dots, x_t, y_1, \dots, y_t]]/(x_1 y_1 + \cdots + x_t y_t)$  also has finite CM type: The change of variables  $x_i = u_i + \sqrt{-1}v_i$ ,  $y_i = u_i - \sqrt{-1}v_i$  shows that  $R \cong R_{1,2d+2}$ .

### §3 Knörrer's periodicity

The results of the previous section on the double branched cover imply that if  $M$  and  $N$  are indecomposable MCM modules over  $R$  and  $R^\sharp$ , respectively, then  $M^{\sharp\flat}$  and  $N^{\flat\sharp}$  both decompose into precisely two indecomposable MCM modules. However, we do not yet know whether this splitting occurs on the way up or the way down. In this section we clarify this point, and use the result to prove Knörrer's theorem that the MCM modules over  $R$  are in bijection with those over the *double* double branched cover  $R^{\sharp\sharp}$ .

**8.21 Notation.** We keep all the notations of the last section, so that  $(S, \mathfrak{n}, k)$  is a complete regular local ring,  $f \in \mathfrak{n}^2$  is a non-zero element, and  $R = S/(f)$  is the corresponding complete hypersurface singularity. In addition, we assume throughout this section that  $k$  is an *algebraically closed* field of characteristic different from 2.

We first prove a sort of converse to Lemma 8.16.

**8.22 Lemma.** *Let  $M$  be a MCM  $R$ -module such that  $M \cong \text{syz}_1^R M$ . Then  $M \cong \text{cok}(\varphi_0, \varphi_0)$  for an  $n \times n$  matrix  $\varphi_0$  satisfying  $\varphi_0^2 = f I_n$ .*

*Proof.* We may assume that  $M$  is indecomposable, and write  $M = \text{cok}(\varphi: G \rightarrow F, \psi: F \rightarrow G)$  by Theorem 8.7. By assumption there is an equivalence of matrix factorizations  $(\alpha, \beta): (\varphi, \psi) \rightarrow (\psi, \varphi)$ , i.e. a commutative diagram of free  $S$ -modules

$$\begin{array}{ccccc}
 F & \xrightarrow{\psi} & G & \xrightarrow{\varphi} & F \\
 \alpha \downarrow & & \downarrow \beta & & \downarrow \alpha \\
 G & \xrightarrow{\varphi} & F & \xrightarrow{\psi} & G
 \end{array}$$

with  $\alpha$  and  $\beta$  isomorphisms. Thus  $\text{cok}(\beta\alpha, \alpha\beta)$  is an automorphism of  $M$ . Since  $M$  is indecomposable and  $R$  is complete,  $\text{End}_R(M)$  is a nc-local ring. Furthermore,  $\text{End}_R(M)/\text{rad}\text{End}_R(M) \cong k$  since  $k$  is algebraically closed. Hence we may write

$$(\beta\alpha, \alpha\beta) = (1_F, 1_G) + (\rho_1, \rho_2)$$

with  $\text{cok}(\rho_1, \rho_2) \in \text{rad}\text{End}_R(M)$ . In particular  $\alpha\rho_1 = \rho_2\alpha$  and  $\beta\rho_2 = \rho_1\beta$ .

Choose a (convergent) power series representing  $(1+x)^{-1/2}$  and set

$$\begin{aligned}\alpha' &= \alpha(1_F + \rho_1)^{-1/2} = (1_G + \rho_2)^{-1/2}\alpha \\ \beta' &= \beta(1_G + \rho_2)^{-1/2} = (1_F + \rho_1)^{-1/2}\beta.\end{aligned}$$

Then the homomorphism of matrix factorizations  $(\alpha', \beta'): (\varphi, \psi) \rightarrow (\psi, \varphi)$  satisfies  $\beta'\alpha' = 1_F$  and  $\alpha'\beta' = 1_G$ . Finally choose an automorphism  $\gamma$  of the free module  $F \cong S^{(n)} \cong G$  such that  $\gamma^2 = \alpha'$ . Then

$$\varphi_0 := \gamma\psi\gamma = \gamma^{-1}\varphi\gamma^{-1}$$

satisfies  $\varphi_0^2 = fI_n$  and  $\text{cok}(\varphi_0, \varphi_0) \cong M$ . □

Let  $R^\sharp = S[[z]]/(f+z^2)$  be the double branched cover of the previous section. Then  $R^\sharp$  carries an involution  $\sigma$ , which fixes  $S$  and sends  $z$  to  $-z$ . Denote by  $R^\sharp[\sigma]$  the *twisted group ring* of the two-element group generated by  $\sigma$  (cf. Chapter 5), i.e.  $R^\sharp[\sigma] = R^\sharp \oplus (R^\sharp \cdot \sigma)$  as  $R^\sharp$ -modules, with multiplication

$$(r + s\sigma)(r' + s'\sigma) = (rr' + s\sigma(s')) + (rs' + s\sigma(r'))\sigma.$$

The modules over  $R^\sharp[\sigma]$  are precisely the  $R^\sharp$ -modules carrying a compatible action of the involution  $\sigma$ . We will call a  $R^\sharp[\sigma]$ -module  $N$  *maximal Cohen-Macaulay* (MCM, as usual) if it is MCM as an  $R^\sharp$ -module.

Let  $N$  be a finitely generated  $R^\sharp[\sigma]$ -module, and set

$$N^+ = \{x \in M \mid \sigma(x) = x\}$$

$$N^- = \{x \in M \mid \sigma(x) = -x\}.$$

Then  $N = N^+ \oplus N^-$  as  $R^\sharp$ -modules. If  $N$  is a MCM  $R^\sharp[\sigma]$ -module, then it follows that  $N^+$  and  $N^-$  are MCM modules over  $(R^\sharp)^+ = S$ , i.e. free  $S$ -modules of finite rank.

**8.23 Definition.** Let  $R$ ,  $R^\sharp$ , and  $R^\sharp[\sigma]$  be as above.

- (i) Let  $N$  be a MCM  $R^\sharp[\sigma]$ -module. Define a MCM  $R$ -module  $\mathcal{A}(N)$  as follows: Multiplication by  $z$ , resp.  $-z$ , defines an  $S$ -linear map between finitely generated free  $S$ -modules

$$\varphi: N^+ \longrightarrow N^-, \quad \text{resp.} \quad \psi: N^- \longrightarrow N^+$$

which together constitute a matrix factorization of  $f$ . Set

$$\mathcal{A}(N) = \text{cok}(\varphi, \psi).$$

- (ii) Let  $M$  be a MCM  $R$ -module, and define a MCM  $R^\sharp$ -module  $\mathcal{B}(M)$  with compatible  $\sigma$ -action as follows: Write  $M = \text{cok}(\varphi: G \longrightarrow F, \psi: F \longrightarrow G)$  with  $F$  and  $G$  finitely generated free  $S$ -modules. Set

$$\mathcal{B}(M) = G \oplus F,$$

with multiplication by  $z$  defined via

$$z(x, y) = (-\psi(y), \varphi(x))$$

and  $\sigma$ -action

$$\sigma(x, y) = (x, -y).$$

**8.24 Proposition.** *The mappings  $\mathcal{A}(-)$  and  $\mathcal{B}(-)$  induce mutually inverse bijections between the isomorphism classes of MCM  $R$ -modules and the isomorphism classes of MCM  $R^\sharp[\sigma]$ -modules having no direct summand isomorphic to  $R^\sharp$ .*

*Proof.* It is easy to verify that  $\mathcal{A}(R^\sharp) = \text{cok}(1, f) = 0$  (here  $R^\sharp$  has the natural  $\sigma$ -action), and that  $\mathcal{A}\mathcal{B}$  and  $\mathcal{B}\mathcal{A}$  are naturally the identities otherwise.  $\square$

In fact  $\mathcal{A}$  and  $\mathcal{B}$  can be used to define equivalences of categories between the MCM  $R^\sharp[\sigma]$ -modules and the matrix factorizations of  $f$ , though we will not need this fact.

**8.25 Lemma.** *Let  $M$  be a MCM  $R$ -module. Then*

$$M^\sharp \cong \mathcal{B}(M)$$

as  $R^\sharp$ -modules, ignoring the action of  $\sigma$  on the right-hand side. Thus  $M^\sharp$  admits the structure of a  $R^\sharp[\sigma]$ -module for every MCM  $R$ -module  $M$ .

*Proof.* Write  $M = \text{cok}(\varphi: G \rightarrow F, \psi: F \rightarrow G)$ , so that  $\mathcal{B}(M) = G \oplus F$  as  $S$ -modules, with  $z(x, y) = (-\psi(y), \varphi(x))$ . On the other hand, by Lemma 8.14,

$$M^\sharp \cong \text{cok} \left( \left( \begin{array}{cc} \psi & -z 1_G \\ z 1_F & \varphi \end{array} \right), \left( \begin{array}{cc} \varphi & z 1_F \\ -z 1_G & \psi \end{array} \right) \right).$$

Choose bases for the free modules to write

$$M^\sharp \cong (R^\sharp)^{(n)} \oplus (R^\sharp)^{(n)} / \text{span}((\psi(u), -zu), (zu, \varphi(u)))$$

where  $u$  runs over  $(R^\sharp)^{(n)}$ . Now  $R^\sharp \cong S \oplus S \cdot z$  as  $S$ -modules, so writing  $u = v + wz$  gives

$$M^\sharp \cong \frac{S^{(n)} \oplus S^{(n)} \oplus S^{(n)} \oplus S^{(n)}}{\text{span}((\psi(v), 0, 0, -v), (0, \psi(w), fw, 0), (0, v, \varphi(v), 0, 0), (-fw, 0, 0, \varphi(w)))}$$

as  $v$  and  $w$  run over  $S^{(n)}$ . Multiplication by  $z$  on this representation of  $M^\sharp$  is defined by

$$z(s_1, s_2, s_3, s_4) = (-f s_2, s_1, -f s_4, s_3)$$

for  $s_1, s_2, s_3, s_4 \in S^{(n)}$ . We therefore define a homomorphism of  $R^\sharp$ -modules  $M^\sharp \rightarrow \mathcal{B}(M)$  by

$$(s_1, s_2, s_3, s_4) \mapsto (-f s_4 - \psi(s_1), -f s_2 - \varphi(s_3)).$$

This is easily checked to be well-defined and surjective, hence an isomorphism of  $R^\sharp$ -modules.  $\square$

**8.26 Proposition.** *Let  $N$  be a stable MCM  $R^\sharp$ -module. Then  $N$  is in the image of  $(-)^\sharp$ , that is,  $N \cong M^\sharp$  for some MCM  $R$ -module  $M$ , if and only if  $N \cong \text{syz}_1^{R^\sharp} N$ .*

*Proof.* If  $N \cong M^\sharp$  and  $N$  is stable, then  $N \cong \text{syz}_1^{R^\sharp} N$  by Lemma 8.14(iii). For the converse, it suffices to show that if  $N$  is an indecomposable MCM  $R^\sharp$ -module such that  $N \cong \text{syz}_1^{R^\sharp} N$ , then  $N$  has the structure of an  $R^\sharp[\sigma]$ -module. Indeed, in that case  $N \cong \mathcal{B}(\mathcal{A}(N)) \cong \mathcal{A}(N)^\sharp$  by Proposition 8.24 and Lemma 8.25, so that  $N$  is in the image of  $(-)^\sharp$ .

By assumption, there is an isomorphism of  $R^\sharp$ -modules  $\alpha: N \rightarrow \text{syz}_1^{R^\sharp} N$ , which induces an isomorphism  $\beta = \text{syz}_1^{R^\sharp}(\alpha): \text{syz}_1^{R^\sharp} N \rightarrow N$ . As  $N$  is indecomposable,  $R^\sharp$  is complete, and  $k$  is algebraically closed we may, as in Lemma 8.22, assume that

$$\beta\alpha = 1_N + \rho,$$

where  $\rho \in \text{rad End}_{R^\sharp}(N)$ . Choose again a convergent power series for  $(1 + x)^{-1/2}$ , and set

$$\tilde{\alpha} = \alpha(1_N + \rho)^{-1/2}.$$

Then  $\tilde{\alpha}$  itself induces an isomorphism  $\tilde{\beta} = \text{syz}_1^{R^\sharp}(\tilde{\alpha}): \text{syz}_1^{R^\sharp} N \longrightarrow N$ , which is easily seen to be

$$\tilde{\beta} = (1_N + \rho)^{-1/2} \beta$$

so that  $\tilde{\beta}\tilde{\alpha} = 1_N$ . Therefore  $\tilde{\alpha}$  defines an action of  $\sigma$  on  $N$ , whence  $N$  has a structure of  $R^\sharp[\sigma]$ -module.  $\square$

Now we can say exactly which modules decompose upon sharpening or flatting.

**8.27 Proposition.** *Keep all the notation of 8.21. In particular,  $k$  is an algebraically closed field of characteristic not equal to 2.*

- (i) *Let  $M$  be an indecomposable non-free MCM  $R$ -module. Then  $M^\sharp$  is indecomposable if, and only if,  $M \cong \text{syz}_1^R M$ . In this case  $M^\sharp \cong N \oplus \text{syz}_1^{R^\sharp} N$  for an indecomposable  $R^\sharp$ -module  $N$  such that  $N \not\cong \text{syz}_1^{R^\sharp} N$ .*
- (ii) *Let  $N$  be a non-free indecomposable MCM  $R^\sharp$ -module. Then  $N^\flat$  is indecomposable if, and only if,  $N \cong \text{syz}_1^{R^\sharp} N$ . In this case  $N^\flat \cong M \oplus \text{syz}_1^R M$  for an indecomposable  $R$ -module  $M$  such that  $M \not\cong \text{syz}_1^R M$ .*

*Proof.* First let  ${}_R M$  be indecomposable, MCM, and non-free. If  $M \cong \text{syz}_1^R M$ , then  $M \cong \text{cok}(\varphi, \varphi)$  for some  $\varphi$  by Lemma 8.22, so that by Lemma 8.14

$$\begin{aligned} M^\sharp &\cong \text{cok} \left( \begin{pmatrix} \varphi & -z 1_F \\ z 1_F & \varphi \end{pmatrix}, \begin{pmatrix} \varphi & z 1_F \\ -z 1_F & \varphi \end{pmatrix} \right) \\ &\cong \text{cok}(\varphi + iz 1_F, \varphi - iz 1_F) \oplus \text{cok}(\varphi - iz 1_F, \varphi + iz 1_F) \end{aligned}$$

is decomposable, where  $i$  is a square root of  $-1$  in  $k$ . Conversely, suppose  $M^\sharp \cong N_1 \oplus N_2$  for non-zero MCM  $R^\sharp$ -modules  $N_1$  and  $N_2$ . Then

$$N_1^\flat \oplus N_2^\flat \cong M^{\sharp\flat} \cong M \oplus \text{syz}_1^R M$$

by Proposition 8.15. Since  $M$  is indecomposable and  $R$  is complete, by KRS we may interchange  $N_1$  and  $N_2$  if necessary to assume that  $N_1^b \cong M$  and  $N_2^b \cong \text{syz}_1^R M$ . Note that  $N_1$  is stable since  $M$  is not free. Then  $\text{syz}_1^R(N_1^b) \cong N_1^b$  by Lemma 8.16(ii), so

$$M \cong N_1^b \cong \text{syz}_1^R(N_1^b) \cong \text{syz}_1^R M,$$

as desired.

Next let  $N$  be a non-free indecomposable MCM  $R^\sharp$ -module. By Proposition 8.26, if  $N \cong \text{syz}_1^{R^\sharp} N$  then  $N \cong M^\sharp$  for some  ${}_R M$ , whence

$$N^b \cong M^{\sharp b} \cong M \oplus \text{syz}_1^R M$$

is decomposable by Proposition 8.15. The converse is shown as above.

To complete the proof of (i), suppose  $M \cong \text{syz}_1^R M$ , so that  $M^\sharp \cong N \oplus \text{syz}_1^{R^\sharp} N$  for some  ${}_R N$ . Then  $M^{\sharp b} \cong M \oplus \text{syz}_1^R M$  has exactly two indecomposable direct summands, so  $N^b$  must be indecomposable. Hence  $N \not\cong \text{syz}_1^{R^\sharp} N$  by the part of (ii) we have already proved. The last sentence of (ii) follows similarly.  $\square$

**8.28 Definition.** In the notation of 8.21, set

$$R^{\sharp\sharp} = S[[u, v]]/(f + uv).$$

(Since we assume  $k$  is algebraically closed of characteristic not 2, this is isomorphic to  $(R^\sharp)^\sharp$ .) For a MCM  $R$ -module  $M = \text{cok}(\varphi: G \rightarrow F, \psi: F \rightarrow G)$ , we define a MCM  $R^{\sharp\sharp}$ -module  $M^{\times}$  by

$$M^{\times} = \text{cok} \left( \left( \begin{array}{cc} \varphi & -v 1_F \\ u 1_G & \psi \end{array} \right), \left( \begin{array}{cc} \psi & v 1_G \\ -u 1_F & \varphi \end{array} \right) \right).$$

Here we continue our convention (cf. 8.13) of using  $1_F$  and  $1_G$  for the identity maps on the free  $S[[u, v]]$ -modules induced from  $F$  and  $G$ .

We leave verification of the next lemma as an exercise.

**8.29 Lemma.** *Keep the notation of the Definition.*

- (i)  $(M^\#)^\# \cong M^{\times} \oplus \text{syz}_1^{R^\#}(M^{\times})$ .
- (ii)  $(M^{\times})^{bb} \cong M \oplus \text{syz}_1^R M$ .
- (iii)  $(\text{syz}_1^R M)^{\times} \cong \text{syz}_1^{R^\#}(M^{\times})$ .

Now we can prove a more precise version of Theorem 8.18.

**8.30 Theorem** (Knörrer). *The association  $M \mapsto M^{\times}$  defines a bijection between the isomorphism classes of indecomposable non-free MCM modules over  $R$  and over  $R^\#$ .*

*Proof.* Let  $M$  be a non-free indecomposable MCM  $R$ -module. Then  $M^\#$  splits into precisely two indecomposable direct summands by Proposition 8.27(i), so that  $M^{\times}$  is indecomposable by Lemma 8.29(i).

If  $M'$  is another indecomposable MCM  $R$ -module with  $(M')^{\times} \cong M^{\times}$ , then by Lemma 8.29(ii) we have either  $M' \cong M$  or  $M' \cong \text{syz}_1^R M$ . Assume  $M \not\cong M' \cong \text{syz}_1^R M$ . Then by Proposition 8.27  $M^\#$  is indecomposable. Therefore the two indecomposable direct summands of  $M^\#$  are non-isomorphic by Proposition 8.27 again. It follows from Lemma 8.29(i) and (iii) that

$$M^{\times} \not\cong \text{syz}_1^{R^\#}(M^{\times}) \cong (\text{syz}_1^R M)^{\times} \cong (M')^{\times},$$

a contradiction.

Finally let  $N$  be an indecomposable non-free MCM  $R^{\#\#}$ -module. We must show that  $N$  is a direct summand of  $M^{\times}$  for some  ${}_R M$ . From Lemma 8.29(i) we find

$$\begin{aligned} (N^{bb})^{\#\#} &\cong (N^{bb})^{\times} \oplus \operatorname{syz}_1^{R^{\#\#}}((N^{bb})^{\times}) \\ &\cong (N^{bb} \oplus \operatorname{syz}_1^{R^{\#\#}}(N^{bb}))^{\times}. \end{aligned}$$

On the other hand,

$$\begin{aligned} (N^{bb})^{\#\#} &\cong \left( (N^b)^{b\#} \right)^{\#} \\ &\cong \left( N^b \oplus \operatorname{syz}_1^{R^{\#}}(N^b) \right)^{\#} \\ &\cong N^{b\#} \oplus \operatorname{syz}_1^{R^{\#}}(N^{b\#}) \\ &\cong N^{(2)} \oplus (\operatorname{syz}_1^{R^{\#}} N)^{(2)}. \end{aligned}$$

Hence  $N$  is in the image of  $(-)^{\times}$ . □

We will not prove Knörrer's stronger result than in fact  $M \longleftrightarrow M^{\times}$  induces an equivalence between the stable categories of MCM modules; see [Knö87] for details.

## §4 Exercises

**8.31 Exercise.** Prove that commutativity of one of the squares in the diagram (8.5.1) implies commutativity of the other.

**8.32 Exercise.** Prove that a matrix factorization  $(\varphi, \psi)$  is reduced if and only if all entries of  $\varphi$  and  $\psi$  are in the maximal ideal  $\mathfrak{n}$  of  $S$ .

**8.33 Exercise.** Verify exactness of the sequence (8.5.2).

**8.34 Exercise.** Let  $\Lambda$  be a ring, not necessarily commutative, with exactly one maximal left ideal, and let  $M$  and  $N$  be left  $\Lambda$ -modules. If  $M \oplus N$  has a direct summand isomorphic to  ${}_{\Lambda}\Lambda$ , then either  $M$  or  $N$  has a direct summand isomorphic to  ${}_{\Lambda}\Lambda$ . Is this still true if, instead,  $\Lambda$  has exactly one maximal two-sided ideal?

**8.35 Exercise.** Fill in the details of the proofs of Proposition 8.6 and Theorem 8.7.

**8.36 Exercise.** Let  $(S, \mathfrak{n}, k)$  be a complete local ring, let  $f \in \mathfrak{n}^2 \setminus \{0\}$ , and put  $g = uf$ , where  $u$  is a unit of  $R$ . If  $k$  is closed under square roots and has characteristic different from 2, show that  $S[[z]]/(f + z^2) \cong S[[z]]/(g + z^2)$ .

**8.37 Exercise.** Prove that  $z$  is a non-zerodivisor of  $R^{\sharp} = S[[z]]/(f + z^2)$ .

**8.38 Exercise.** Prove that the natural map  $S[z]/(f + z^2) \rightarrow S[[z]]/(f + z^2)$  is an isomorphism. In particular,  $R^{\sharp}$  is a free  $S$ -module with basis  $\{1, z\}$ . Show by example that if  $S$  is not assumed to be complete then  $S[[z]]/(f + z^2)$  need not be finitely generated as an  $S$ -module.

**8.39 Exercise.** With notation as in the proof of (iii) of Lemma 8.16, show that the sequence

$$S[[z]]^{(n)} \xrightarrow{zI_n - \varphi} S[[z]]^{(n)} \rightarrow N \rightarrow 0$$

is exact. (Hint: Use Exercise 8.38 and choose bases.)

**8.40 Exercise.** Prove Lemma 8.29.

## *Hypersurfaces with finite CM type*

In this chapter we will show that the complete, equicharacteristic hypersurface singularities with finite CM type are exactly the ADE singularities. In any characteristic but two, Theorem 9.7 shows that such a hypersurface of dimension  $d \geq 2$  is the double branched cover of one with dimension  $d - 1$ . In Theorem 9.8, proved in 1987 by Buchweitz, Greuel, Knörrer and Schreyer [Knö87, BGS87], we restrict to rings having an algebraically closed coefficient field of characteristic different from 2, 3, and 5, and show that finite CM type is equivalent to *simplicity* (Definition 9.1), and to being an ADE singularity. We'll also prove Herzog's theorem [Her78b]: Gorenstein rings of finite CM type are abstract hypersurfaces. In §4 we derive matrix factorizations for the Kleinian singularities (two-dimensional ADE hypersurface singularities). At the end of the chapter we will discuss the situation in characteristics 2, 3 and 5. Later, in Chapter 10, we will see how to eliminate the assumption that  $R$  be complete, and also we'll weaken "algebraically closed" to "perfect".

We will do a few things in slightly greater generality than we will need in this chapter, so that they will apply also to the study of *countable* CM type in Chapter 13.

### §1 Simple singularities

**9.1 Definition.** Let  $(S, \mathfrak{n})$  be a regular local ring, and let  $R = S/(f)$ , where  $0 \neq f \in \mathfrak{n}^2$ . We call  $R$  a *simple* (respectively *countably simple*) singular-

ity (relative to the presentation  $R = S/(f)$ ) provided there are only finitely (respectively countably) many ideals  $L$  of  $S$  such that  $f \in L^2$ .

**9.2 Theorem** (Buchweitz, Greuel and Schreyer [BGS87]). *Let  $R = S/(f)$ , where  $(S, \mathfrak{n})$  is a regular local ring and  $0 \neq f \in \mathfrak{n}^2$ . If  $R$  has finite (respectively countable) CM type, then  $R$  is a simple (respectively countably simple) singularity.*

*Proof.* Let  $\mathcal{M}$  be a set of representatives for the equivalence classes of reduced matrix factorizations of  $f$ . By Theorem 8.7,  $\mathcal{M}$  is finite (respectively countable). For each  $(\varphi, \psi) \in \mathcal{M}$ , let  $L(\varphi, \psi)$  be the ideal of  $S$  generated by the entries of  $[\varphi | \psi]$ . Let  $\mathcal{S}$  be the set of ideals that are ideal sums of finite subsets of  $\{L(\varphi, \psi) \mid (\varphi, \psi) \in \mathcal{M}\}$ . Then  $\mathcal{S}$  is finite (respectively countable), and we claim that every proper ideal  $L$  for which  $f \in L^2$  belongs to  $\mathcal{S}$ . To see this, let  $a_0, \dots, a_r$  generate  $L$ , and write  $f = a_0 b_0 + \dots + a_r b_r$ , with  $b_i \in L$ . For  $0 \leq s \leq r$ , let  $f_s = a_0 b_0 + \dots + a_s b_s$ . Put  $\sigma_0 = a_0$ ,  $\tau_0 = b_0$ , and for  $1 \leq s \leq r$  define, inductively, a  $2^s \times 2^s$  matrix factorization of  $f_s$  by

$$(9.2.1) \quad \sigma_s = \begin{bmatrix} a_s I_{2^{s-1}} & \sigma_{s-1} \\ \tau_{s-1} & -b_s I_{2^{s-1}} \end{bmatrix} \quad \text{and} \quad \tau_s = \begin{bmatrix} b_s I_{2^{s-1}} & \sigma_{s-1} \\ \tau_{s-1} & -a_s I_{2^{s-1}} \end{bmatrix}.$$

Letting  $\sigma = \sigma_r$  and  $\tau = \tau_r$ , we see that  $(\sigma, \tau)$  is a reduced matrix factorization of  $f$  with  $L(\sigma, \tau) = L$ . Then  $(\sigma, \tau)$  is equivalent to  $(\varphi_1, \psi_1)^{(n_1)} \oplus \dots \oplus (\varphi_t, \psi_t)^{(n_t)}$ , where  $(\varphi_j, \psi_j) \in \mathcal{M}$  and  $n_j > 0$  for each  $j$ . Finally, we have  $L = L(\sigma, \tau) = \sum_{j=1}^t L(\varphi_j, \psi_j) \in \mathcal{S}$ .  $\square$

The following lemma, together with the Weierstrass Preparation Theorem, will show that every simple singularity of dimension  $d \geq 2$  is a double branched cover of a  $(d - 1)$ -dimensional simple singularity:

**9.3 Lemma.** *Let  $(S, \mathfrak{n}, k)$  be a regular local ring and  $R = S/(f)$  a singularity with  $d = \dim(R) \geq 1$ .*

(i) *Suppose  $R$  is a simple singularity. Then:*

a)  *$R$  is reduced, i.e. for each  $g \in \mathfrak{n}$  we have  $g^2 \nmid f$ .*

b)  $e(R) \leq 3$ .

c) *If  $k$  is algebraically closed and  $d \geq 2$ , then  $e(R) = 2$ .*

(ii) *Suppose  $R$  is a countably simple singularity and  $k$  is uncountable. Then:*

a) *For each  $g \in \mathfrak{n}$  we have  $g^3 \nmid f$ .*

b)  $e(R) \leq 3$ .

c) *If  $k$  is algebraically closed and  $d \geq 2$ , then  $e(R) = 2$ .*

*Proof.* (ia) Suppose  $f$  has a repeated factor, so that we can write  $f = g^2h$ , where  $g \in \mathfrak{n}$  and  $h \in S$ . Now  $\dim(S/(g)) = d \geq 1$ , so  $S/(g)$  has infinitely many ideals. Therefore  $S$  has infinitely many ideals that contain  $g$ , and  $f$  is in the square of each, a contradiction.

(iia) Suppose  $f$  is divisible by the cube of some  $g \in \mathfrak{n}$ . Let  $\Lambda \subset R$  be a complete set of coset representatives for  $k^\times$ . If  $S/(g)$  is not a DVR, let  $\{\xi, \eta\}$  be part of a minimal generating set for  $\mathfrak{n}/(g)$ , and lift  $\xi, \eta$  to  $x, y \in \mathfrak{n}$ . For  $\lambda \in \Lambda$ , put  $L_\lambda = (x + \lambda y, g)$ . We have  $L_\lambda \neq L_\mu$  if  $\lambda \neq \mu$ , for if  $L = L_\lambda = L_\mu$  and  $\lambda \not\equiv \mu \pmod{\mathfrak{m}}$ , then  $L$  contains  $(\lambda - \mu)y$ , hence  $y$ , and hence  $x$ ; this means that  $L/(g) = (\xi, \eta) = (\xi + \lambda\eta)$ , contradicting the choice of  $\xi$  and  $\eta$ . For each  $\lambda \in k$ , we have  $f \in L_\lambda^3 \subseteq L_\lambda^2$ , a contradiction.

Now assume that  $S/(g)$  is a DVR. Then  $\dim(S) = 2$  and  $g \notin \mathfrak{n}^2$ . Write  $\mathfrak{n} = (g, h)$ , and note that  $g$  and  $h$  are non-associate irreducible elements of  $S$ . For  $\lambda \in \Lambda$ , put  $I_\lambda = (g + \lambda h^2, gh)$ . Suppose  $I := I_\lambda = I_\mu$  with  $\lambda \neq \mu$ . Then  $I = (g, h^2)$ . Writing

$$(9.3.1) \quad g = (g + \lambda h^2)p + ghq,$$

with  $p, q \in S$ , we see that  $g \mid \lambda h^2 p$ , whence  $g \mid p$ . Write  $p = gs$ , with  $s \in S$ , plug this into (9.3.1), and cancel  $g$ , getting the equation  $1 = (g + \lambda h^2)s + hq \in \mathfrak{n}$ , a contradiction. Thus  $L_\lambda \neq L_\mu$  when  $\lambda \neq \mu$ . Moreover, we have

$$g^3 = g(g + \lambda h^2)^2 - \lambda h(g + \lambda h^2)(gh) - \lambda(gh)^2 \in I_\lambda^2$$

for each  $\lambda$ . Thus  $f \in I_\lambda^2$  for each  $\lambda$ , again contradicting countable simplicity.

(ib) and (iib) Suppose  $e(R) \geq 4$ . Then  $f \in \mathfrak{n}^4$  (cf. Exercise 9.29). If  $L$  is any ideal such that  $\mathfrak{n}^2 \subsetneq L \subsetneq \mathfrak{n}$ , then  $f \in L^2$ . These ideals correspond to non-zero proper subspaces of the  $k$ -vector space  $\mathfrak{n}/\mathfrak{n}^2$ , so there are infinitely (respectively uncountably) many of them, a contradiction.

(ic) and (iic) We know that  $e(R)$  is either 2 or 3, so we suppose  $e(R) = 3$ , that is,  $f \in \mathfrak{n}^3 \setminus \mathfrak{n}^4$ . Let  $f^*$  be the coset of  $f$  in  $\mathfrak{n}^3/\mathfrak{n}^4$ . Then  $f^*$  is a cubic form in the associated graded ring  $G = k \oplus \mathfrak{n}/\mathfrak{n}^2 \oplus \mathfrak{n}^2/\mathfrak{n}^3 \oplus \dots = k[x_0, \dots, x_d]$ , where  $(x_0, \dots, x_d) = \mathfrak{n}$ . The zero set  $Z$  of  $f^*$  is an infinite (respectively uncountable) subset of  $\mathbb{P}_k^d$ . Fix a point  $\lambda = (\lambda_0 : \lambda_1 : \dots : \lambda_d) \in Z$ , and let  $\{L_1, \dots, L_d\}$  be a basis for the  $k$ -vector space of linear forms vanishing at  $\lambda$ . These forms generate the ideal of  $G$  consisting of polynomials vanishing at  $\lambda$ , and it follows that

$$(9.3.2) \quad f^* \in (L_1, \dots, L_d)(x_0, \dots, x_d)^2 G.$$

Lift each  $L_i \in \mathfrak{n}/\mathfrak{n}^2$  to a element  $\tilde{L}_i \in \mathfrak{n} \setminus \mathfrak{n}^2$ , and put  $I_\lambda = (\tilde{L}_1, \dots, \tilde{L}_d)S + \mathfrak{n}^2$ . Pulling (9.3.2) back to  $S$  and using the fact that  $f^* = f + \mathfrak{n}^4$ , we get  $f \in (\tilde{L}_1, \dots, \tilde{L}_d)\mathfrak{n}^2 + \mathfrak{n}^4$ , whence  $f \in I_\lambda^2$ . Since  $I_\lambda \neq I_\mu$  if  $\lambda$  and  $\mu$  are distinct points of  $Z$ , we have contradicted simplicity (respectively countable simplicity).  $\square$

The next lemma will be used to control the order of the higher-degree terms in the defining equations of (countably) simple singularities:

**9.4 Lemma.** *Let  $R = S/(f)$  be a hypersurface singularity of positive dimension, where  $(S, \mathfrak{n}, k)$  is a regular local ring and  $0 \neq f \in \mathfrak{n}^2$ . Assume either that  $k$  is infinite and  $R$  is a simple singularity, or that  $k$  is uncountable and  $R$  is a countably simple singularity. Let  $\alpha, \beta \in \mathfrak{n}$ . Then  $f \notin (\alpha, \beta^2)^3$ .*

*Proof.* Suppose  $f \in (\alpha, \beta^2)^3$ . Let  $\Lambda \subseteq S$  be a complete set of representatives for the residue field  $k$ , and for each  $\lambda \in \Lambda$  put  $I_\lambda = (\alpha + \lambda\beta^2, \beta^3)$ . One checks easily that  $(\alpha, \beta^2)^3 \subseteq I_\lambda^2$  (Exercise 9.31). Therefore it will suffice to show that  $I_\lambda \neq I_\mu$  whenever  $\lambda$  and  $\mu$  are distinct elements of  $\Lambda$ .

Suppose  $\lambda, \mu \in \Lambda$ ,  $\lambda \neq \mu$ , and  $I_\lambda = I_\mu$ . Since  $\lambda - \mu$  is a unit of  $S$ , we see that  $\beta^2 \in I_\lambda$ . Writing  $\beta^2 = s(\alpha + \lambda\beta^2) + t\beta^3$ , with  $s, t \in S$ , we see that  $\beta^2(1 - t\beta) \in (\alpha + \lambda\beta^2)$ . Therefore  $\beta^2 \in (\alpha + \lambda\beta^2)$ , and it follows that  $I_\lambda = (\alpha + \lambda\beta^2)$ . Now  $f \in (\alpha, \beta^2)^3 = I_\lambda^3 = (\alpha + \lambda\beta^2)^3$ , and this contradicts (ia) or (iia) of Lemma 9.3.  $\square$

## §2 Hypersurfaces in good characteristics

For this section  $k$  is an algebraically closed field and  $d$  is a positive integer. Put  $S = k[[x_0, \dots, x_d]]$  and  $\mathfrak{n} = (x_0, \dots, x_d)$ . We will consider  $d$ -dimensional hypersurface singularities: rings of the form  $S/(f)$ , where  $0 \neq f \in \mathfrak{n}^2$ .

We refer to [Lan02, Chapter IV, Theorem 9.2] for the following version of the Weierstrass Preparation Theorem:

**9.5 Theorem (WPT).** *Let  $(D, \mathfrak{m})$  be a complete local ring, and let  $g \in D[[x]]$ . Suppose  $g = a_0 + a_1x + \dots + a_e x^e + \text{higher degree terms}$ , with  $a_0, a_1, \dots, a_{e-1} \in \mathfrak{m}$  and  $a_e \in D \setminus \mathfrak{m}$ . Then there exist  $b_1, \dots, b_e \in \mathfrak{m}$  and a unit  $u \in D[[x]]$  such that  $g = (x^e + b_1x^{e-1} + \dots + b_e)u$ .*

The conclusion is equivalent to asserting that  $D[[x]]/(g)$  is a free  $D$ -module of rank  $e$ , with basis  $1, x, \dots, x^{e-1}$ .

**9.6 Corollary.** *Let  $\ell$  be an infinite field, and let  $g$  be a non-zero power series in  $S = \ell[[x_0, \dots, x_n]]$ ,  $n \geq 1$ . Assume that the order  $e$  of  $g$  is at least 2 and is not a multiple of  $\text{char}(\ell)$ . Then, after a change of coordinates, we have  $g = (x_n^e + b_2x_n^{e-2} + b_3x_n^{e-3} + \dots + b_{e-1}x_n + b_e)u$ , where  $b_2, \dots, b_e$  are non-units of  $D := \ell[[x_0, \dots, x_{n-1}]]$  and  $u$  is a unit of  $S$ .*

*Proof.* We will make a linear change of variables, following Zariski and Samuel [ZS75, p. 147], so that Theorem 9.5 applies, with respect to the new variables. Write  $g = g_e + g_{e+1} + \dots$ , where each  $g_j$  is a homogeneous polynomial of degree  $j$  and  $g_e \neq 0$ . Then  $x_n g_e \neq 0$ , and, since  $\ell$  is infinite, there is a point  $(c_0, c_1, \dots, c_n) \in \ell^{n+1}$  such that  $x_n g_e$  does not vanish when evaluated at  $(c_0, \dots, c_n)$ . Then  $c_n \neq 0$ , and since  $x_n g_e$  is homogeneous we

can scale and assume that  $c_n = 1$ . We change variables as follows:

$$\varphi: x_i \mapsto \begin{cases} x_i + c_i x_n & \text{if } i < n \\ x_n & \text{if } i = n. \end{cases}$$

Now,  $\varphi(g) = \varphi(g_e) + \text{higher-order terms}$ , and  $\varphi(g_e)$  contains the term  $g_e(c_0, c_1, \dots, c_{n-1}, 1)x_n^e = cx_n^e$ , where  $c \in \ell^\times$ . It follows that  $\varphi(g)$  has the form required in Theorem 9.5, with  $x = x_n$ . Replacing  $g$  by  $\varphi(g)$ , we now have  $g = (x_n^e + b_1x_n^{e-1} + \dots + b_e)u$ , where the  $b_i$  are non-units of  $D$  and  $u$  is a unit of  $S$ . Finally, we make the substitution  $x_n \mapsto x_n - \frac{b_1}{e}x_n^{e-1}$  to eliminate the coefficient  $b_1$ .  $\square$

Here is the main theorem of this chapter, due to Buchweitz-Greuel-Schreyer and Knörrer [Knö87, BGS87].

**9.7 Theorem.** *Let  $k$  be an algebraically closed field of characteristic different from 2, and put  $S = k[[x_0, \dots, x_d]]$ , where  $d \geq 2$ . Let  $R = S/(f)$ , where  $0 \neq f \in (x_0, \dots, x_d)^2$ . Then  $R$  has finite CM type if and only if there is a non-zero element  $g \in (x_0, x_1)^2 k[[x_0, x_1]]$  such that  $k[[x_0, x_1]]/(g)$  has finite CM type and  $R \cong S/(g + x_2^2 + \dots + x_d^2)$ .*

*Proof.* The “if” direction follows from Theorem 8.18 and induction on  $d$ . For the converse, we assume that  $R$  has finite CM type. Then  $R$  is a simple singularity (Theorem 9.2), and (ic) of Lemma 9.3 implies that  $e(R) = 2$ . Since  $\text{char}(k) \neq 2$ , we may assume, by Corollary 9.6, that  $f = x_d^2 + b$ , with  $b \in (x_0, \dots, x_{d-1})^2 k[[x_0, x_1, \dots, x_{d-1}]]$ . (The unit  $u$  in the conclusion of the corollary does not affect the isomorphism class of  $R$ .) Note that  $b \neq 0$ , by (ia) of Lemma 9.3. Then  $R = A^\#$ , where  $A = k[[x_0, x_1, \dots, x_{d-1}]]/(b)$ .

Now Theorem 8.18 implies that  $A$  has finite CM type. If  $d = 2$  we set  $g = b$ , and we're done. Otherwise, after a change of coordinates we have  $b = (x_{d-1}^2 + c)u$ , where  $c \in (x_0, \dots, x_{d-2})^2 k[[x_0, \dots, x_{d-2}]] \setminus \{0\}$  and  $u$  is a unit of  $k[[x_0, x_1, \dots, x_{d-1}]]$ . Now  $f = (x_d^2 u^{-1} + x_{d-1}^2 + c)u$ . Since  $\text{char}(k) \neq 2$ , Corollaries A.32 and 1.9 provide a unit  $v$  such that  $v^2 = u^{-1}$ . After replacing  $x_d$  by  $x_d v$  and discarding the unit  $u$ , we now have  $R \cong S/(c + x_{d-1}^2 + x_d^2)$ . Rinse and repeat!  $\square$

If the characteristic of  $k$  is different from 2, 3 and 5, we get a more explicit version of the theorem.

**9.8 Theorem.** *Let  $k$  be an algebraically closed field with  $\text{char}(k) \neq 2, 3, 5$ , let  $d \geq 1$ , and let  $R = k[[x, y, x_2, \dots, x_d]]/(f)$ , where  $0 \neq f \in (x, y, x_2, \dots, x_d)^2$ .*

*These are equivalent:*

- (i)  $R$  has finite CM type.
- (ii)  $R$  is a simple singularity.
- (iii)  $R \cong k[[x, y, x_2, \dots, x_d]]/(g + x_2^2 + \dots + x_d^2)$ , where  $g \in k[x, y]$  defines a one-dimensional ADE singularity (cf. Chapter 4, §3).

A consequence of this theorem is that, in this context, simplicity of  $R$  depends only on the isomorphism class of  $R$ , not on the presentation  $R = S/(f)$ . The proof of the theorem will occupy the rest of the section.

*Proof.* (i)  $\implies$  (ii) by Theorem 9.2.

(ii)  $\implies$  (iii): Suppose first that  $d \geq 2$ ; then  $e(R) = 2$  by (ic) of Lemma 9.3. By Corollary 9.6, we may assume that  $f = x_d^2 + b$ , where  $b$  is a non-zero non-unit of  $k[[x_0, x_1, \dots, x_{d-1}]]$ . Then  $R = A^\#$ , where  $A = k[[x_0, x_1, \dots, x_{d-1}]]/(b)$ .

Simplicity passes from  $R$  to  $A$ : If there were an infinite number of ideals  $L_i$  of  $k[[x_0, x_1, \dots, x_{d-1}]]$  with  $b \in L_i^2$  for each  $i$ , we would have  $x_d^2 + b \in (L_i S + x_d S)^2$  for each  $i$ , where  $S = k[[x_0, \dots, x_d]]$ . Since  $(L_i S + x_d S) \cap k[[x_0, x_1, \dots, x_{d-1}]] = L_i$ , the extended ideals would be distinct, contradicting simplicity of  $R$ . Thus we can continue the process, dropping dimensions till we reach dimension one. It suffices, therefore, to prove that (ii)  $\implies$  (iii) when  $d = 1$ .

Changing notation, we set  $S = k[[y, x]]$  and  $\mathfrak{n} = (y, x)S$ . (The silly ordering of the variables stems from the choice of the normal forms for the ADE singularities in Chapter 4, §3.) We have a simple power series  $f \in \mathfrak{n}^2 \setminus \{0\}$ , and we want to show that  $R = S/(f)$  is an ADE singularity. We will follow Yoshino's proof of [Yos90, Proposition 8.5] closely, adding a few details and making a few necessary modifications (some of them to accommodate non-zero characteristic  $p > 5$ ).

Suppose first that  $e(R) = 2$ . By Corollary 9.6, we may assume that  $f = x^2 + g$ , where  $g \in yk[[y]]$ . Then  $g \neq 0$  by (ia) of Lemma 9.3, and we write  $g = x^t u$ , where  $u \in k[[x]]^\times$ . Then  $t \geq 2$ , else  $R$  would be a discrete valuation ring. Replacing  $f$  by  $u^{-1}f$ , we now have  $f = u^{-1}x^2 + y^t$ . Now we let  $v \in k[[y]]^\times$  be a square root of  $u^{-1}$  (using Corollary A.32) and make the change of variables  $x \mapsto vx$ . Then  $f = x^2 + y^t$ , so  $R$  is an  $(A_{t-1})$ -singularity.

Before taking on the more challenging case  $e(R) = 3$ , we pause for a primer on tangent directions of an analytic curve. Given any non-zero, non-unit power series  $g \in K[[x, y]]$ , where  $K$  is any algebraically closed field, let  $g_e$  be the initial form of  $g$ . Thus  $g_e$  is a non-zero homogeneous polynomial of degree  $e \geq 1$  and  $g = g_e + \text{higher-degree forms}$ . We can factor  $g_e$  as a

product of powers of distinct linear forms:

$$g_e = \ell_1^{m_1} \cdots \ell_h^{m_h},$$

where each  $m_i > 0$  and the linear forms  $\ell_i$  are not associates in  $K[x, y]$ . (To do this, dehomogenize, then factor, then homogenize.) The *tangent lines* to the curve  $g = 0$  are the lines  $\ell_i = 0$ ,  $1 \leq i \leq h$ . We will need the “Tangent Lemma” (cf. [Abh90, p. 141]):

**9.9 Lemma.** *Let  $g$  be a non-zero non-unit in  $K[[x, y]]$ , where  $K$  is an algebraically closed field. If  $g$  is irreducible, then  $g$  has a unique tangent line.*

*Proof.* Let  $e$  be the order of  $g$ . By Theorem 9.5 we may assume that  $g = y^e + b_1 y^{e-1} + \cdots + b_{e-1} y + b_e$ , where the  $b_i \in B := K[[x]]$ . Since  $x^i \mid b_i$  (else the order of  $g$  would be smaller than  $e$ ), we may write

$$g = y^e + c_1 x y^{e-1} + \cdots + c_{e-1} x^{e-1} y + c_e x^e,$$

with  $c_i \in B$ . Let us assume that the curve  $g = 0$  has more than one tangent line. Then we can factor the leading form

$$g_e = y^e + c_1(0) x y^{e-1} + \cdots + c_{e-1}(0) x^{e-1} y + c_e(0) x^e$$

as a product of linear factors  $y - a_i x$  with not all  $a_i$  equal. Dehomogenizing (setting  $x = 1$ ), we have

$$y^e + c_1(0) y^{e-1} + \cdots + c_{e-1}(0) y + c_e(0) = \prod_{i=1}^e (y - a_i).$$

By grouping the factors intelligently, we can write

$$(9.9.1) \quad y^e + c_1(0) y^{e-1} + \cdots + c_{e-1}(0) y + c_e(0) = p q,$$

where  $p$  and  $q$  are relatively prime monic polynomials of positive degree.

Put  $z = \frac{y}{x}$ . Then  $z$  is transcendental over  $B$ , and we have

$$g = x^e h, \text{ where } h = z^e + c_1 z^{e-1} + \cdots + c_{e-1} z + c_e \in B[z].$$

By (9.9.1), the reduction of  $h$  modulo  $xB$  factors as the product of two relatively prime monic polynomials of positive degree. Since  $B$  is Henselian (cf. Theorem A.31 and Corollary 1.9), we can write

$$h = (z^m + u_1 z^{m-1} + \cdots + u_0)(z^n + v_1 z^{n-1} + \cdots + v_0).$$

with  $u_i, v_j \in B$  and with both  $m$  and  $n$  positive. Then

$$g = (y^m + u_1 x y^{m-1} + \cdots + u_0 x^m)(y^n + v_1 x y^{n-1} + \cdots + v_0 x^n)$$

is the desired factorization of  $g$ . □

The lemma is exemplified by the nodal cubic  $g = y^2 - x^2 - x^3 = y^2 - x^2(1+x)$ , which, though irreducible in  $K[x, y]$ , factors in  $K[[x, y]]$  as long as  $\text{char}(K) \neq 2$ . It has two distinct tangent lines,  $x+y=0$  and  $x-y=0$ ; and indeed it factors: If  $h$  is a square root of  $1+x$  (obtained from the binomial expansion of  $(1+x)^{\frac{1}{2}}$ , or via Hensel's Lemma: Corollaries 1.9 and A.32), then  $g = (y+xh)(y-xh)$ .

Now assume  $e(R) = 3$ , and write  $f = x^3 + xa + b$ , where  $a, b \in yk[[y]]$ . Since  $f$  has order 3, we have  $a \in y^2 k[[y]]$  and  $b \in y^3 k[[y]]$ .

**9.10 Case.**  $f$  is irreducible.

Then  $b \neq 0$ . The initial form  $f_3$  of  $f$  is a power of a single linear form by Lemma 9.9, and it follows that  $f_3 = x^3$ . Therefore the order of  $a$  is at least

3, and  $b$  has order  $n \geq 4$ . If  $a = 0$  we have  $f = x^3 + uy^n$ , where  $u \in k[[y]]^\times$ . By extracting a cube root of  $u^{-1}$  (using Corollary A.32), we may assume that  $f = x^3 + y^n$ . Now Lemma 9.4 implies that  $n$  must be 4 or 5, and  $R$  is an  $(E_6)$  or  $(E_8)$  singularity. If  $a \neq 0$  we can assume that  $f = x^3 + uxy^m + y^n$ , where  $m \geq 3$  and  $u \in k[[y]]^\times$ . Suppose for a moment that  $m = 3$  and  $n \geq 5$ . Then one can find a root  $\xi \in k[[y]]^\times$  of  $T^3 + uT^2 + y^{2n-9} = 0$  by lifting the simple root  $-\bar{u}$  of  $T^3 - \bar{u}T^2 \in k[T]$ . One checks that then  $x = \xi^{-1}y^{m-3}$  is a root of  $f$ , contradicting irreducibility. Thus either  $m \geq 4$  or  $n = 4$ .

Suppose  $n = 4$ , so  $f = x^4 + uxy^m + y^4$ . After the transformation  $y \mapsto y - \frac{1}{4}uxy^{m-3}$ ,  $f$  takes the form

$$f = \begin{cases} x^3 + bx^2y^2 + y^4 & (b \in k[[x, y]]) & \text{if } m > 3 \\ vx^3 + cx^2y^2 + y^4 & (c \in k[[x, y]], v \in k[[x, y]]^\times) & \text{if } m = 3. \end{cases}$$

If  $m = 3$ , we use the transformation  $x \mapsto v^{\frac{1}{3}}x$  to eliminate the unit  $v$  (modifying  $c$  along the way). Thus in either case we have  $f = x^3 + bx^2y^2 + y^4$ , and now the transformation  $x \mapsto x - \frac{1}{3}by^2$  puts  $f$  into the form  $f = x^3 + wy^4$ , where  $w \in k[[x, y]]^\times$ . Replacing  $y$  by  $w^{\frac{1}{4}}y$ , we obtain the  $(E_6)$ -singularity.

Now assume that  $n \neq 4$  (and, consequently,  $m \geq 4$ ). Lemma 9.4 implies that  $n = 5$ . The transformation  $y \mapsto y - \frac{1}{5}uxy^{m-4}$  (with a unit adjustment to  $x$  if  $m = 4$ ) puts  $f$  in the form  $x^3 + bx^2y^3 + y^5$ . The change of variable  $x \mapsto x - \frac{1}{3}by^3$  now transforms  $f$  to  $x^3 + wy^5$ , where  $w \in k[[x, y]]^\times$ . On replacing  $y$  with  $w^{\frac{1}{5}}y$ , we obtain the  $(E_8)$  singularity, finishing this case.

**9.11 Case.**  $f$  is reducible but has only one tangent line.

Changing notation, we may assume that  $f = x(x^2 + ax + b)$ , where  $a$  and  $b$  are non-units of  $k[[y]]$ . As before,  $x^3$  must be the initial form of  $f$ , so

$f = x(x^2 + cxy^2 + dy^3)$ , where  $c, d \in k[[y]]$ . By Lemma 9.4  $d$  must be a unit. After replacing  $y$  by  $d^{\frac{1}{3}}y$ , we can write  $f = x(x^2 + exy^2 + y^3)$ , where  $e \in k[[y]]$ . Next do the change of variable  $y \mapsto y - \frac{1}{3}ex$  to eliminate the  $y^2$  term. Now  $f = x(ux^2 + y^3)$ , where  $u \in k[[x, y]]^\times$ . Replacing  $x$  by  $u^{-\frac{1}{2}}x$ , we have, up to a unit multiple, an  $(E_7)$  singularity.

**9.12 Case.**  $f$  is reducible and has more than one tangent line.

Write  $f = \ell q$ , where  $\ell$  is linear in  $x$  and  $q$  is quadratic. If the tangent line of  $\ell$  happens to be a tangent line of  $q$ , then, by Lemma 9.9,  $q$  factors as a product of two linear polynomials with distinct tangent lines. In any case, we can write  $f = (x - r)(x^2 + sx + t)$ , where  $r, s, t \in yk[[y]]$ , and where the tangent line to  $x - r$  is *not* a tangent line of  $x^2 + sx + t$ . After the usual changes of variables and multiplication by a unit, we may assume that  $f = (x - r)(x^2 + y^n)$ , where  $n \geq 2$ . If  $n = 2$ , then  $f$  is a product of three distinct lines, and we get  $(D_4)$ . Assume now that  $n \geq 3$ . Then  $x = 0$  is the tangent line to  $x^2 + y^n$  and therefore cannot be the tangent line to  $x - r$ . Hence  $r = uy$  for some unit  $u \in k[[y]]^\times$ . We make the coordinate change  $y \mapsto x - uy$ . Now  $f = y(ax^2 + bxy^{n-1} + cy^n)$ , where  $a$  and  $c$  are units of  $k[[x, y]]$ . Better, up to the unit multiple  $c$ , we have  $f = y(ac^{-1}x^2 + bc^{-1}xy^{n-1} + y^n)$ . Replace  $x$  by  $(ac^{-1})^{\frac{1}{2}}$ ; now  $f = y(x^2 + dxy^{n-1} + y^n)$ . After the change of coordinates  $x \mapsto x - \frac{1}{2}dy^{n-1}$ , we have  $f = y(x^2 - \frac{1}{4}d^2y^{2n-2} + y^n)$ . Since  $2n - 2 > n$ , we can rewrite this as  $f = y(x^2 + ey^n)$ , where  $e \in k[[x, y]]^\times$ . Finally, we factor out  $e$  and replace  $x$  by  $e^{-\frac{1}{2}}x$ , bringing  $f$  into the form  $y(x^2 + y^n)$ , the equation for the  $(D_{n+2})$  singularity.

To finish the cycle and complete the proof of Theorem 9.8, we now show that (iii)  $\implies$  (i). If  $d = 1$  we invoke Corollary 8.19. Assuming inductively

that  $k[[x_0, \dots, x_r]]/(g + z_2^2 + \dots + z_r^2)$  has finite CM type for some  $r \geq 1$ , we see, by (ii) of Theorem 8.18, that  $k[[x_0, \dots, x_{r+1}]]/(g + z_2^2 + \dots + z_{r+1}^2)$  has finite CM type as well.  $\square$

**9.13 Remark.** Inspecting the proof, we see that the demonstration of (ii)  $\implies$  (iii) in the one-dimensional case of Theorem 9.8 uses only the following three properties of a simple singularity  $R = S/(f)$ , where  $(S, \mathfrak{n})$  is a two-dimensional regular local ring:

- (i)  $R$  is reduced;
- (ii)  $e(R) \leq 3$ ; and
- (iii)  $f \notin (\alpha, \beta^2)^3$  for every  $\alpha, \beta \in \mathfrak{n}$ .

Since the one-dimensional ADE hypersurfaces obviously satisfy these properties, it follows that  $f$  defines a simple singularity if and only if these three conditions are satisfied.

### §3 Gorenstein singularities of finite CM type

In this section we will prove Herzog's theorem [Her78b] stating that the rings of the title are hypersurfaces. Before giving the proof, we establish the following result (also from [Her78b]) of independent interest. Recall that a MCM module  $M$  is *stable* provided it has no non-zero free summands.

**9.14 Lemma.** *Let  $(R, \mathfrak{m})$  be a CM local ring, let  $M$  be a stable MCM  $R$ -module, and let  $N = \text{syz}_1^R(M)$ .*

- (i)  $N$  is stable.

(ii) Assume  $M$  is indecomposable, that  $\text{Ext}_R^1(M, R) = 0$ , and that  $R_{\mathfrak{p}}$  is Gorenstein for every prime ideal  $\mathfrak{p}$  of  $R$  with  $\text{height } \mathfrak{p} \leq 1$ . Then  $N$  is indecomposable.

*Proof.* We have a short exact sequence

$$(9.14.1) \quad 0 \longrightarrow N \longrightarrow F \longrightarrow M \longrightarrow 0 ,$$

where  $F$  is free and  $N \subseteq \mathfrak{m}F$ . Let  $(\underline{x}) = (x_1, \dots, x_d)$  be a maximal  $R$ -regular sequence in  $\mathfrak{m}$ . Since  $M$  is MCM,  $(\underline{x})$  is  $M$ -regular, and it follows that  $\underline{x}N = \underline{x}F \cap N$ . The map  $N/\underline{x}N \rightarrow F/\underline{x}F$  is therefore injective, and it gives an injection  $N/\underline{x}N \hookrightarrow \mathfrak{m}F/\underline{x}F$ . Since  $(\underline{x})$  is a maximal  $N$ -regular sequence,  $\mathfrak{m} \in \text{Ass } N/\underline{x}N$ , so  $\mathfrak{m} \in \text{Ass}(\mathfrak{m}F/\underline{x}F) = \text{Ass}(\mathfrak{m}/(\underline{x}))$ . It follows that  $\mathfrak{m}/\underline{x}$  is an unfaithful  $R/(\underline{x})$ -module and hence that  $N/\underline{x}N$  is unfaithful too. But then  $N/\underline{x}N$  cannot have  $R/(\underline{x})$  as a direct summand, and item (i) follows.

For the second statement, we note at the outset that both  $M$  and  $N$  are reflexive  $R$ -modules, by Corollary A.16. We dualize (9.14.1), using the vanishing of  $\text{Ext}_R^1(M, R)$ , to get an exact sequence

$$(9.14.2) \quad 0 \longrightarrow M^* \longrightarrow F^* \longrightarrow N^* \longrightarrow 0 .$$

Suppose  $N = N_1 \oplus N_2$ , with both summands non-zero. By (i), neither summand is free. Since  $N$  is reflexive, neither  $N_1^*$  nor  $N_2^*$  is free, and it follows from (9.14.2) that  $M^*$  decomposes non-trivially. As  $M$  is reflexive, this contradicts indecomposability of  $M$ .  $\square$

**9.15 Theorem** (Herzog). *Let  $(R, \mathfrak{m}, k)$  be a Gorenstein local ring with a bound on the number of generators required for indecomposable MCM modules. Then  $\widehat{R}$  is a hypersurface ring.*

*Proof.* Let  $M = \text{syz}_d^R(k)$ , and write  $M = M_1 \oplus \cdots \oplus M_t$ , where each  $M_i$  is indecomposable and the summands are indexed so that  $M_i \cong R$  if and only if  $i > s$ . By Lemma 9.14,  $\text{syz}_j^R(M)$  is a direct sum of at most  $s$  indecomposable modules for  $j > d$ . (The requisite vanishing of Ext follows from the Gorenstein hypothesis.) It follows that the Betti numbers of  $k$  are bounded. The fact that they have polynomial growth implies, by [Gul80], that  $\widehat{R}$  is a complete intersection, and now [Tat57] implies that  $\widehat{R}$  is a hypersurface.  $\square$

Combining Theorem 9.15 with Theorem 9.8, we have classified finite CM type for complete Gorenstein algebras over an algebraically closed field. See Corollary 10.17 for the final improvement.

**9.16 Theorem.** *Let  $k$  be an algebraically closed field of characteristic different from 2, 3, and 5. Let  $(R, \mathfrak{m}, k)$  be a Gorenstein complete local ring containing  $k$  as a coefficient field. If  $R$  has finite CM type, then  $R$  is a complete ADE hypersurface singularity.*

The classification of Theorem 9.16 allows us to verify Conjectures 7.20 and 7.21 in this case.

**9.17 Corollary.** *Let  $R$  be as in Theorem 9.16. Then  $R$  has minimal multiplicity. If  $\text{char}(k) = 0$ , then  $R$  has a rational singularity.*

## §4 Matrix factorizations for the Kleinian singularities

Theorem 6.22 shows that the complete Kleinian singularities  $k[[x, y, z]]/(f)$  have finite CM type, where  $f$  is one of the polynomials listed in Table 6.1

and  $k$  is an algebraically closed field of characteristic not 2, 3, or 5. This was the key step in the classification of Gorenstein rings of finite CM type in the previous section. Given their central importance, it is worthwhile to have a complete listing of the matrix factorizations for the indecomposable MCM modules over these rings.

To describe the matrix factorizations, we return to the setup of Definition 6.5: Let  $G$  be a finite subgroup of  $\mathrm{SL}(2, \mathbb{C})$ , that is, one of the binary polyhedral groups of Theorem 6.11. Let  $G$  act linearly on the power series ring  $S = \mathbb{C}[[u, v]]$ , and set  $R = S^G$ . Then  $R$  is generated over  $\mathbb{C}$  by three invariants  $x(u, v)$ ,  $y(u, v)$ , and  $z(u, v)$ , which satisfy a relation  $z^2 + g(x, y) = 0$  for some polynomial  $g$  depending on  $G$ , so that  $R \cong \mathbb{C}[[x, y, z]]/(z^2 + g(x, y))$ .

Set  $A = \mathbb{C}[[x(u, v), y(u, v)]] \subset R$ . Then  $A$  is a power series ring, in particular a regular local ring. Since  $z^2 \in A$ , we see that as in Chapter 8,  $R$  is a free  $A$ -module of rank 2. Moreover, any MCM  $R$ -module is  $A$ -free as well. It is known [ST54, Coh76] that  $A$  is also a ring of invariants of a finite group  $G' \subset \mathrm{U}(2, \mathbb{C})$ , generated by complex reflections of order 2 and containing  $G$  as a subgroup of index 2.

Let  $V_0, \dots, V_d$  be a full set of the non-isomorphic irreducible representations of  $G$ ; then we know from Corollary 5.20 and Theorem 6.3 that  $M_j = (S \otimes_{\mathbb{C}} V_j)^G$ , for  $j = 0, \dots, d$ , are precisely the direct summands of  $S$  as  $R$ -module and are also precisely the indecomposable MCM  $R$ -modules. To get a handle on the  $M_j$ , we can express them as  $(S \otimes_{\mathbb{C}} \mathrm{Ind}_G^{G'} V_j)^{G'}$ . Being free over  $A$ , each  $M_j$  will have a basis of  $G'$ -invariants. These, and the identities of the representations  $\mathrm{Ind}_G^{G'} V_j$ , are computed in [GSV81].

Now we show how to obtain the matrix factorization corresponding to

each  $M_j$ , following [GSV81]. The proof of the next proposition is a straightforward verification, mimicking the proof (see B.6(i)) that the kernel of the multiplication map  $\mu: B \otimes_A B \rightarrow B$  is generated by all elements of the form  $b \otimes 1 - 1 \otimes b$ . The essential observation is that  $z^2 = -g(x, y) \in A$ .

**9.18 Proposition.** *Let  $\sigma: S \rightarrow S$  be the  $R$ -module endomorphism sending  $z$  to  $-z$ , and let  ${}^\sigma S$  be the  $R$ -module with underlying abelian group  $S$ , but with  $R$ -module structure given by  $r \cdot s = \sigma(r)s$ . Then we have two exact sequences of  $R$ -modules:*

$$0 \longrightarrow {}^\sigma S \xrightarrow{i^-} R \otimes_A S \xrightarrow{p^+} S \longrightarrow 0$$

and

$$0 \longrightarrow S \xrightarrow{i^+} R \otimes_A S \xrightarrow{p^-} {}^\sigma S \longrightarrow 0,$$

where  $i^-(s) = i^+(s) = z \otimes s - 1 \otimes zs$ ,  $j^+(r \otimes s) = rs$ , and  $j^-(r \otimes s) = \sigma(r)s$ .

From this proposition one deduces the following theorem. We omit the details.

**9.19 Theorem.** *Let  $S = \mathbb{C}[[u, v]]$ ,  $G$  a finite subgroup of  $\mathrm{SL}(2, \mathbb{C})$  acting linearly on  $S$ , and  $R = S^G$ . Let  $x$ ,  $y$ , and  $z$  be generating invariants for  $R$  satisfying the relation  $z^2 + g(x, y) = 0$ , and let  $A = \mathbb{C}[[x, y]]$ . Then the  $R$ -free resolution of  $S$  has the form*

$$\cdots \xrightarrow{T^-} R \otimes_A S \xrightarrow{T^+} R \otimes_A S \xrightarrow{T^-} R \otimes_A S \xrightarrow{p^+} S \longrightarrow 0,$$

where

$$T^\pm(r \otimes s) = zr \otimes s \pm r \otimes zs.$$

Moreover, the  $R$ -free resolution of each indecomposable  $R$ -direct summand  $M_j$  of  $S$  is the direct summand of the above resolution of the form

$$\cdots \xrightarrow{T_j^-} R \otimes_A M_j \xrightarrow{T_j^+} R \otimes_A M_j \xrightarrow{T_j^-} R \otimes_A M_j \xrightarrow{p_j^+} M_j \longrightarrow 0.$$

□

In terms of matrices, the resolution and corresponding matrix factorization of the MCM  $R$ -module  $M_j$  can be deduced from the theorem as follows. Let  $\Phi: S \rightarrow S$  denote the  $R$ -linear homomorphism given by multiplication by  $z$ , and let  $\Phi_j: M_j \rightarrow M_j$  be the restriction to  $M_j$ . Then each  $\Phi_j$  is an  $A$ -linear map of free  $A$ -modules. Choose a basis and represent  $\Phi_j$  by an  $n \times n$  matrix  $\varphi_j$  with entries in  $x$  and  $y$ . Then  $\varphi_j^2$  is equal to multiplication by  $z^2 = -g(x, y) \in A$  on  $M_j$ , so that

$$(zI_n - \varphi_j, zI_n + \varphi_j)$$

is a matrix factorization of  $z^2 + g(x, y)$  with cokernel  $M_j$ .

Our task is thus reduced to computing the matrix representing multiplication by  $z$  on each  $M_j$ . As in Chapter 6, we treat each case separately.

**9.20** ( $A_n$ ). We have already computed the presentation matrices of the MCM modules over  $\mathbb{C}[[x, y, z]]/(xz - y^{n+1})$  in Example 5.25, but we illustrate Theorem 9.19 in this easy case before proceeding to the more involved ones below. The cyclic group  $\mathcal{C}_{n+1}$ , generated by

$$\epsilon_{n+1} = \begin{pmatrix} \zeta_{n+1} & 0 \\ 0 & \zeta_{n+1}^{-1} \end{pmatrix},$$

has invariants  $x = u^{n+1} + v^{n+1}$ ,  $y = uv$ , and  $z = u^{n+1} - v^{n+1}$ , satisfying

$$z^2 - (x^2 - 4y^{n+1}) = 0.$$

Set  $A = \mathbb{C}[[x, y]] \subset R = k[[x, y, z]]$ . Then  $A = \mathbb{C}[[u^{n+1} + v^{n+1}, uv]]$  is an invariant ring of the group  $G'$  generated by  $\epsilon_{n+1}$  and the additional reflection  $s = \begin{pmatrix} & 1 \\ 1 & \end{pmatrix}$ .

Let  $V_j$ , for  $j = 0, \dots, n$ , be the irreducible representation of  $\mathcal{C}_{n+1}$  with character  $\chi_j(g) = \zeta_{n+1}^j$ . Then the MCM  $R$ -modules  $M_j = (S \otimes_{\mathbb{C}} V_j)^G$  are generated over  $R$  by the monomials  $u^a v^b$  such that  $b - a \equiv j \pmod{n+1}$ . Over  $A$ , each  $M_j$  is freely generated by  $u^j$  and  $v^{n+1-j}$ . Since

$$zu^j = (u^{n+1} - v^{n+1})u^j = (u^{n+1} + v^{n+1})u^j - 2(uv)^j v^{n+1-j}$$

and

$$zv^{n+1-j} = (u^{n+1} - v^{n+1})v^{n+1-j} = 2(uv)^{n+1-j} u^j - (u^{n+1} + v^{n+1})v^{n+1-j},$$

the matrix  $\varphi_j$  representing the action of  $z$  on  $M_j$  is

$$\varphi_j = \begin{pmatrix} x & 2y^{n+1-j} \\ -2y^j & -x \end{pmatrix}.$$

One checks that  $\varphi_j^2 = (x^2 - 4y^{n+1})I_2$ , so  $(zI_2 - \varphi_j, zI_2 + \varphi_j)$  is the matrix factorization corresponding to  $M_j$ .

Making a linear change of variables, we find that the indecomposable matrix factorizations of the  $(A_n)$  singularity defined by  $x^2 + y^{n+1} + z^2 = 0$  are  $(zI_2 - \varphi_j, zI_2 + \varphi_j)$ , where

$$\varphi_j = \begin{pmatrix} ix & y^{n+1-j} \\ -y^j & -ix \end{pmatrix},$$

for  $j = 0, \dots, n$ , and where  $i$  denotes a square root of  $-1$ .

**9.21** ( $D_n$ ). The dihedral group  $\mathcal{D}_{n-2}$  is generated by

$$\alpha = \begin{pmatrix} \zeta_{2(n-2)} & 0 \\ 0 & \zeta_{2(n-2)}^{-1} \end{pmatrix} \quad \text{and} \quad \beta = \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix},$$

where again  $i$  denotes a square root of  $-1$ . The invariants of  $\alpha$  and  $\beta$  are  $x = u^{2(n-2)} + (-1)^n v^{2(n-2)}$ ,  $y = u^2 v^2$ , and  $z = uv(u^{2(n-2)} - (-1)^n v^{2(n-2)})$ , which satisfy

$$z^2 - y(x^2 - 4(-1)^n y^{n-2}) = 0.$$

Again we set  $A = \mathbb{C}[[x, y]] = \mathbb{C}[[u^{2(n-2)} + (-1)^n v^{2(n-2)}, u^2 v^2]]$  and again  $A$  is the ring of invariants of the group  $G'$  generated by  $\epsilon_{2(n-2)}$ ,  $\tau$ , and  $s = \begin{pmatrix} & 1 \\ 1 & \end{pmatrix}$ .

In the matrices below, we will implicitly make the linear changes of variable necessary to put the defining equation of  $R$  into the form

$$z^2 - (-y(x^2 + y^{n-2})) = 0.$$

Consider first the one-dimensional representation  $V_1$  given by  $\alpha \mapsto 1$  and  $\beta \mapsto -1$ . The MCM  $R$ -module  $M_1 = (S \otimes_{\mathbb{C}} V_1)^G$  has  $A$ -basis  $(uv, u^{2(n-2)} - (-1)^n v^{2(n-2)})$ , and after the change of variable the matrix  $\varphi_1$  for multiplication by  $z$  is

$$\varphi_1 = \begin{pmatrix} 0 & -x^2 - y^{n-1} \\ y & 0 \end{pmatrix}.$$

Next consider the two-dimensional irreducible representations  $V_j$ , for  $j = 2, \dots, n-2$ , given by

$$\alpha \mapsto \begin{pmatrix} \zeta_{2(n-2)}^{j-1} & 0 \\ 0 & \zeta_{2(n-2)}^{-j+1} \end{pmatrix} \quad \text{and} \quad \beta \mapsto \begin{pmatrix} 0 & i^{j-1} \\ i^{j-1} & 0 \end{pmatrix}.$$

For each  $j$ , the corresponding MCM  $R$ -module  $M_j$  has  $A$ -basis  $(u^{j-1}, uv^{2n-j-2}, u^j v, v^{2n-j-3})$ .

The matrix  $\varphi_j$  depends on the parity of  $j$ ; for  $j$  even, it is

$$\varphi_j = \begin{pmatrix} & -xy & -y^{n-1-j/2} \\ & -y^{j/2} & x \\ x & y^{n-1-j/2} & \\ y^{j/2} & -xy & \end{pmatrix}$$

while if  $j$  is odd we have

$$\varphi_j = \begin{pmatrix} & -xy & -y^{n-1-(j-1)/2} \\ & -y^{(j+1)/2} & xy \\ x & y^{n-2-(j-1)/2} & \\ y^{(j-1)/2} & -x & \end{pmatrix}.$$

Finally consider  $V_{n-1}$  and  $V_n$ , which are the irreducible components of the two-dimensional reducible representation

$$\alpha \mapsto \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \beta \mapsto \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}.$$

The MCM  $R$ -modules  $M_{n-1}$  and  $M_n$  have bases  $(uv(u^{n-2} + (-1)^{n+1}v^{n-2}), u^{n-2} + (-1)^n v^{n-2})$  and  $(uv(u^{n-2} + (-1)^n v^{n-2}), u^{n-2} + (-1)^{n+1} v^{n-2})$ , respectively. Again the corresponding matrices  $\varphi_{n-1}$  and  $\varphi_n$  depend on parity: for  $n$  odd we have

$$\varphi_{n-1} = \begin{pmatrix} iy^{(n-1)/2} & -x \\ xy & -iy^{(n-1)/2} \end{pmatrix} \quad \text{and} \quad \varphi_n = \begin{pmatrix} iy^{(n-1)/2} & -xy \\ x & -iy^{(n-1)/2} \end{pmatrix},$$

and for  $n$  even

$$\varphi_{n-1} = \begin{pmatrix} 0 & -x - iy^{(n-2)/2} \\ xy - iy^{n/2} & 0 \end{pmatrix} \quad \text{and} \quad \varphi_n = \begin{pmatrix} 0 & -x + iy^{(n-2)/2} \\ xy + iy^{n/2} & 0 \end{pmatrix}.$$

For the  $E$ -series examples, we suppress the details of the complex reflection group  $G'$  and the  $A$ -bases for the  $M_j$ . See [ST54] and [GSV81].

**9.22 ( $E_6$ ).** The defining equation of the ( $E_6$ ) singularity is  $z^2 - (-x^3 - y^4) = 0$ . For each of the six non-trivial irreducible representations  $V_1, V_2, V_3, V_3^\vee, V_4,$  and  $V_{4^\vee}$ , one can choose  $A$ -bases for  $M_j$  so that multiplication by  $z$  is given by the following matrices. The matrix factorizations for the corresponding MCM  $R$ -modules are given by  $(zI_n - \varphi, zI_n + \varphi)$ .

$$\varphi_1 = \begin{pmatrix} & -x^2 & -y^3 \\ & -y & x \\ x & y^3 & \\ y & -x^2 & \end{pmatrix} \quad \varphi_2 = \begin{pmatrix} & -x^2 & -y^3 & xy^2 \\ & xy & -x^2 & -y^3 \\ & -y^2 & xy & -x^2 \\ x & 0 & y^2 & \\ y & x & 0 & \\ 0 & y & x & \end{pmatrix}$$

$$\varphi_3 = \begin{pmatrix} iy^2 & 0 & -x^2 & 0 \\ 0 & iy^2 & -xy & -x^2 \\ x & 0 & -iy^2 & 0 \\ -y & x & 0 & -iy^2 \end{pmatrix} \quad \varphi_3^\vee = \begin{pmatrix} -iy^2 & 0 & -x^2 & 0 \\ 0 & -iy^2 & -xy & -x^2 \\ x & 0 & iy^2 & 0 \\ -y & x & 0 & iy^2 \end{pmatrix}$$

$$\varphi_4 = \begin{pmatrix} iy^2 & -x^2 \\ x & -iy^2 \end{pmatrix} \quad \varphi_4^\vee = \begin{pmatrix} -iy^2 & -x^2 \\ x & iy^2 \end{pmatrix}$$

**9.23 ( $E_7$ ).** The ( $E_7$ ) singularity is defined by  $z^2 - (-x^3 - xy^3) = 0$ . There are 7 non-trivial irreducible representations  $V_1, \dots, V_7$ , and the matrices  $\varphi_j$  corresponding to multiplication by  $z$  are given below. The matrix factoriza-

tions for the corresponding MCM  $R$ -modules are given by  $(zI_n - \varphi, zI_n + \varphi)$ .

$$\varphi_1 = \begin{pmatrix} & -x^2 & -xy^2 \\ & -y & x \\ x & xy^2 & \\ y & -x^2 & \end{pmatrix} \quad \varphi_2 = \begin{pmatrix} & -x^2 & -xy^2 & x^2y \\ & xy & -x^2 & -xy^2 \\ & -y^2 & xy & -x^2 \\ x & 0 & xy \\ y & x & 0 \\ 0 & y & x \end{pmatrix}$$

$$\varphi_3 = \begin{pmatrix} & & & & 0 & 0 & -x^2 & -xy^2 \\ & & & & 0 & 0 & -xy & x^2 \\ & & & & -x & -y^2 & 0 & xy \\ & & & & -y & x & -x & 0 \\ 0 & -xy & x^2 & xy^2 \\ x & 0 & xy & -x^2 \\ x & y^2 & 0 & 0 \\ y & -x & 0 & 0 \end{pmatrix}$$

$$\varphi_4 = \begin{pmatrix} & xy & -x^2 & -xy^2 \\ & -y^2 & xy & -x^2 \\ & -x & -y^2 & xy \\ 0 & xy & x^2 \\ x & 0 & xy \\ y & x & 0 \end{pmatrix} \quad \varphi_5 = \begin{pmatrix} & -xy & -x^2 \\ & -x & y^2 \\ y^2 & x^2 \\ x & -xy \end{pmatrix}$$

$$\varphi_6 = \begin{pmatrix} 0 & y^3 + x^2 \\ -x & 0 \end{pmatrix} \quad \varphi_7 = \begin{pmatrix} & -x^2 & -xy^2 \\ & -xy & x^2 \\ x & y^2 & \\ y & -x & \end{pmatrix}$$

**9.24** ( $E_8$ ). The defining equation of the ( $E_6$ ) singularity is  $z^2 - (-x^3 - y^5) = 0$ . Here are the matrices  $\varphi_j$  representing multiplication by  $z$  on the 8 non-trivial indecomposable MCM  $R$ -modules. The matrix factorizations are given by  $(zI_n - \varphi, zI_n + \varphi)$ .

$$\varphi_1 = \begin{pmatrix} & -x^2 & -y^4 \\ & -y & x \\ x & y^4 & \\ y & -x^2 & \end{pmatrix} \quad \varphi_2 = \begin{pmatrix} & -x^2 & -y^4 & xy^3 \\ & xy & -x^2 & -y^4 \\ & -y^2 & xy & -x^2 \\ x & 0 & y^3 & \\ y & x & 0 & \\ 0 & y & x & \end{pmatrix}$$

$$\varphi_3 = \begin{pmatrix} & & & & xy & -y^2 & -x^2 & 0 \\ & & & & -y^3 & 0 & 0 & -x \\ & & & & x^2 & 0 & 0 & -y^2 \\ & & & & 0 & x & -y^3 & -y \\ 0 & y^2 & -x & 0 & & & & \\ y^3 & xy & 0 & -x^2 & & & & \\ x & 0 & -y & y^2 & & & & \\ 0 & x^2 & y^3 & 0 & & & & \end{pmatrix}$$

$$\varphi_6 = \begin{pmatrix} & & & & 0 & -y^3 & -x^2 & 0 \\ & & & & -y^2 & 0 & xy & -x^2 \\ & & & & -x & -y^2 & 0 & y^3 \\ & & & & 0 & -x & y^2 & 0 \\ 0 & y^3 & x^2 & -xy^2 & & & & \\ y^2 & 0 & 0 & x^2 & & & & \\ x & 0 & 0 & -y^3 & & & & \\ y & x & -y^2 & 0 & & & & \end{pmatrix} \quad \varphi_7 = \begin{pmatrix} & & -y^3 & -x^2 \\ & & x & -y^2 \\ y^2 & -x^2 & & \\ x & y^3 & & \end{pmatrix}$$

$$\varphi_8 = \begin{pmatrix} & & & -x^2 & xy^2 & -y^4 \\ & & & -y^3 & -x^2 & xy^2 \\ & & & xy & -y^3 & -x^2 \\ x & y^2 & 0 & & & \\ 0 & x & y^2 & & & \\ y & 0 & x & & & \end{pmatrix}$$

**9.25 Remark.** We observe that the forms above for the indecomposable matrix factorizations over the two-dimensional ADE singularities make it easy to find the indecomposable matrix factorizations in dimension one. When the matrix  $\varphi$  (involving only  $x$  and  $y$ ) has the distinctive anti-diagonal block shape, the pair of non-zero blocks constitutes (up to a sign) an indecomposable matrix factorization for the one-dimensional ADE polynomial in  $x$  and  $y$ . When the matrix  $\varphi$  does not have block form,  $(\varphi, -\varphi)$  is an indecomposable matrix factorization. See §3 of Chapter 12.

## §5 Bad characteristics

Here we describe, without proofs, the classification of hypersurfaces of finite CM type in characteristics 2, 3 and 5. If the characteristic of  $k$  is different from 2, Theorem 9.7 reduces the classification to the case of dimension one. We quote the following two theorems due to Greuel and Kröning [GK90] (cf. also the paper [KS85] by Kiyek and Steinke):

**9.26 Theorem** (Characteristic 3). *Let  $k$  be an algebraically closed field of characteristic 3, let  $d \geq 1$ , and let  $R = k[[x, y, x_2, \dots, x_d]]/(f)$ , where  $0 \neq f \in (x, y, x_2, \dots, x_d)^2$ . Then  $R$  has finite CM type if and only if  $R \cong k[[x, y, x_2, \dots, x_d]]/(g + x_2^2 + \dots + x_d^2)$ , where  $g \in k[x, y]$  is one of the following:*

$$(A_n): x^2 + y^{n+1}, \quad n \geq 1$$

$$(D_n): x^2y + y^{n-1}, \quad n \geq 4$$

$$(E_6^0): x^3 + y^4$$

$$(E_6^1): x^3 + y^4 + x^2y^2$$

$$(E_7^0): x^3 + xy^3$$

$$(E_7^1): x^3 + xy^3 + x^2y^2$$

$$(E_8^0): x^3 + y^5$$

$$(E_8^1): x^3 + y^5 + x^2y^3$$

$$(E_8^2): x^3 + y^5 + x^2y^2$$

**9.27 Theorem** (Characteristic 5). *Let  $k$  be an algebraically closed field of characteristic 5, let  $d \geq 1$ , and let  $R = k[[x, y, x_2, \dots, x_d]]/(f)$ , where  $0 \neq f \in (x, y, x_2, \dots, x_d)^2$ . Then  $R$  has finite CM type if and only if  $R \cong k[[x, y, x_2, \dots, x_d]]/(g + x_2^2 + \dots + x_d^2)$ , where  $g \in k[x, y]$  is one of the following:*

$$(A_n): x^2 + y^{n+1}, \quad n \geq 1$$

$$(D_n): x^2y + y^{n-1}, \quad n \geq 4$$

$$(E_6): x^3 + y^4$$

$$(E_7): x^3 + xy^3$$

$$(E_8^0): x^3 + y^5$$

$$(E_8^1): x^3 + y^5 + xy^4$$

In characteristics different from two, notice that  $S[[u, v]]/(f + u^2 + v^2) \cong S[[u, v]]/(f + uv)$ , via the transformation  $u \mapsto \frac{u+v}{2}$ ,  $v \mapsto \frac{u-v}{2\sqrt{-1}}$ . Thus, if one does not mind skipping a dimension, one can transfer finite CM type up and down along the iterated double branched cover  $R^{\sharp\sharp} = S[[u, v]]/(f + uv)$ , where  $R = S/(f)$ . Remarkably, this works in characteristic two as well.

**9.28 Theorem** (Solberg, Greuel and Kroning [Sol89, GK90]). *Let  $k$  be an algebraically closed field of arbitrary characteristic, let  $d \geq 3$ , and let  $R = k[[x_0, \dots, x_d]]/(f)$ , where  $0 \neq f \in (x_0, \dots, x_d)^2$ . Then  $R$  has finite CM type if and only if there exists a non-zero non-unit  $g \in k[[x_0, \dots, x_{d-2}]]$  such that  $k[[x_0, \dots, x_{d-2}]]/(g)$  has finite CM type and  $R \cong k[[x_0, \dots, x_d]]/(g + x_{d-1}x_d)$ .*

Solberg proved the “if” direction in his 1987 dissertation [Sol89]. He showed, in fact, that, for any non-zero non-unit  $g \in k[[x_0, \dots, x_{d-2}]]$ , the hypersurface ring  $k[[x_0, \dots, x_{d-2}]]/(g)$  has finite CM type if and only if  $k[[x_0, \dots, x_d]]/(g + x_{d-1}x_d)$  has finite CM type. The proof, which uses the theory of AR sequences (cf. Chapter 12), is quite unlike the proof in characteristics different from two, in that there seems to be no nice correspondence between MCM  $R$ -modules and MCM  $R^{\#}$ -modules (such as in Theorem 8.30). In 1988 Greuel and Kröning [GK90] used deformation theory to show that if  $R$  as in the theorem has finite CM type, then  $R \cong k[[x_0, \dots, x_d]]/(g + x_{d-1}x_d)$  for a suitable non-zero non-unit element  $g \in k[[x_0, \dots, x_{d-2}]]$ , thereby establishing the converse of the theorem.

In order to finish the classification of complete hypersurface singularities of finite CM type in characteristic two, one needs to classify those singularities in dimensions one and two. The normal forms are itemized in Section 5 of [Sol89] and in [GK90] and depend on earlier work of Artin [Art77], Artin and Verdier [AV85], and Kiyek and Steinke [KS85].

## §6 Exercises

**9.29 Exercise.** Let  $(S, \mathfrak{n})$  be a regular local ring, and  $f \in \mathfrak{n}^r \setminus \mathfrak{n}^{r+1}$ . Show that the hypersurface ring  $S/(f)$  has multiplicity  $r$ . (Hint: pass to the associated graded ring and compute the Hilbert-Samuel function of  $S/(f)$ . See Appendix A for an alternative approach.)

**9.30 Exercise.** Let  $S$  be a regular local ring and  $R = S/(f)$  a singularity of dimension at least two. If  $R$  is simple, prove that  $R$  is an integral domain.

---

**9.31 Exercise.** In the notation of Lemma 9.4, prove that  $(\alpha^3, \alpha^2\beta^2, \alpha\beta^4, \beta^6) \subseteq (\alpha + \lambda\beta^2, \beta^3)^2$  for any  $\lambda$ . (Hint: start with  $\beta^6$  and work backwards.)

# 10

## *Ascent and descent*

We have seen in Chapter 9 that the hypersurface rings  $(R, \mathfrak{m}, k)$  of finite Cohen-Macaulay type have a particularly nice description when  $R$  is complete,  $k$  is algebraically closed and  $R$  contains a field of characteristic different from 2, 3, and 5. In this section we will see to what extent finite Cohen-Macaulay type ascends to and descends from faithfully flat extensions such as the completion or Henselization, and how it behaves with respect to residue field extension. In 1987 F.-O. Schreyer [Sch87] conjectured that a local ring  $(R, \mathfrak{m}, k)$  has finite Cohen-Macaulay type if and only if the  $\mathfrak{m}$ -adic completion  $\widehat{R}$  has finite Cohen-Macaulay type. We have already seen that Schreyer's conjecture is true in dimension one (Corollary 4.17). We shall see that the “if” direction holds in general, and the “only if” direction holds when  $R$  is excellent and Cohen-Macaulay. For rings that are neither excellent nor CM, there are counterexamples (cf. 10.11). Schreyer also conjectured ascent and descent of finite CM type along extensions of the residue field (cf. Theorem 10.13 below). We shall prove descent in general, and ascent in the separable case. Inseparable extensions, however, can cause problems (cf. Example 10.15). We will revisit some of these issues in Chapter 16, where we consider ascent and descent of *bounded* CM type.

## §1 Descent

Recall from Chapter 2 that for a finitely generated  $R$ -module  $M$ , we denote by  $\text{add}_R(M)$  the full subcategory of  $R\text{-mod}$  containing modules that are isomorphic to direct summands of direct sums of copies of  $M$ . When  $A \rightarrow B$  is a faithfully flat ring extension and  $M$  and  $N$  are finitely generated  $R$ -modules, we have  $M \in \text{add}_R(N)$  if and only if  $S \otimes_R M \in \text{add}_S(S \otimes_R N)$  (Proposition 2.18). Furthermore, when  $R$  is local and  $M$  is finitely generated,  $\text{add}_R(M)$  contains only finitely many isomorphism classes of indecomposable modules (Theorem 2.2).

Here is the main result of this section ([Wie98, Theorem 1.5]).

**10.1 Theorem.** *Let  $(R, \mathfrak{m}) \rightarrow (S, \mathfrak{n})$  be a flat local homomorphism such that  $S/\mathfrak{m}S$  is Cohen-Macaulay. If  $S$  has finite Cohen-Macaulay type, then so has  $R$ .*

*Proof.* The hypothesis that the closed fiber  $S/\mathfrak{m}S$  is CM guarantees that  $S \otimes_R M$  is a MCM  $S$ -module whenever  $M$  is a MCM  $R$ -module (cf. Exercise 10.18). Let  $\mathcal{U}$  be the class of MCM  $S$ -modules that occur in direct-sum decompositions of extended MCM modules; thus  $Z \in \mathcal{U}$  if and only if there is a MCM  $R$ -module  $X$  such that  $Z$  is isomorphic to an  $S$ -direct-summand of  $S \otimes_R X$ . Let  $Z_1, \dots, Z_t$  be a complete set of representatives for isomorphism classes of indecomposable modules in  $\mathcal{U}$ . Choose, for each  $i$ , a MCM  $R$ -module  $X_i$  such that  $Z_i \mid S \otimes_R X_i$ , and put  $Y = X_1 \oplus \dots \oplus X_t$ .

Suppose now that  $L$  is an indecomposable MCM  $R$ -module. Then  $S \otimes_R L \cong Z_1^{(a_1)} \oplus \dots \oplus Z_t^{(a_t)}$  for suitable non-negative integers  $a_i$ , and it follows that  $S \otimes_R L$  is isomorphic to a direct summand of  $S \otimes_R Y^{(a)}$ , where  $a =$

$\max\{a_1, \dots, a_t\}$ . By Proposition 2.18,  $L$  is a direct summand of a direct sum of copies of  $Y$ . Then, by Theorem 2.2, there are only finitely many possibilities for  $L$ , up to isomorphism.  $\square$

By the way, the class  $\mathcal{U}$  in the proof of Theorem 10.1 is *not* necessarily the class of all MCM  $S$ -modules. For example, consider the extension  $R = k[[t^2]] \longrightarrow k[[t^2, t^3]] = S$ ; in this case, the only extended MCM modules are the free ones. (Cf. also Exercise 13.29). The first order of business in the next section will be to find situations where this unfortunate behavior cannot occur, that is, where *every* MCM  $S$ -module is a direct summand of an extended MCM module.

## §2 Ascent to the completion

It's a long way to the completion of a local ring, so we will make a stop at the Henselization. In this section and the next, we will need to understand the behavior of finite CM type under direct limits of étale and, more generally, unramified extensions. We will recall the basic definitions here and refer to Appendix B for details, in particular, for reconciling our definitions with others in the literature.

**10.2 Definition.** A local homomorphism of local rings  $(R, \mathfrak{m}, k) \longrightarrow (S, \mathfrak{n}, \ell)$  is *unramified* provided  $S$  is essentially of finite type over  $R$  (that is,  $S$  is a localization of some finitely generated  $R$ -algebra) and the following properties hold.

- (i)  $\mathfrak{m}S = \mathfrak{n}$ , and

(ii)  $S/\mathfrak{m}S$  is a finite separable field extension of  $R/\mathfrak{m}$ .

If, in addition,  $\varphi$  is flat, then we say  $\varphi$  is *étale*. (We say also that  $S$  is an *unramified*, respectively, *étale* extension of  $R$ .) Finally, a *pointed étale neighborhood* is an étale extension  $(R, \mathfrak{m}, k) \rightarrow (S, \mathfrak{n}, \ell)$  inducing an isomorphism on residue fields.

By Proposition B.9, properties (i) and (ii) are equivalent to the single requirement that the *diagonal* map  $\mu: S \otimes_R S \rightarrow R$  (taking  $s_1 \otimes s_2$  to  $s_1 s_2$ ) splits as  $S \otimes_R S$ -modules (equivalently,  $\ker(\mu)$  is generated by an idempotent).

It turns out (see [Ive73] for details) that the isomorphism classes of pointed étale neighborhoods of a local ring  $(R, \mathfrak{m})$  form a direct system. The remarkable fact that makes this work is that if  $R \rightarrow S$  and  $R \rightarrow T$  are pointed étale neighborhoods then there is *at most one* homomorphism  $S \rightarrow T$  making the obvious diagram commute.

**10.3 Definition.** The *Henselization*  $R^h$  of  $R$  is the direct limit of a set of representatives of the isomorphism classes of pointed étale neighborhoods of  $R$ .

The Henselization is, conveniently, a Henselian ring (cf. Chapter 1 §2 and Appendix A, §3).

Suppose  $R \hookrightarrow S$  is a flat local homomorphism. As in Chapter 4 (§1), we say that a finitely generated  $S$ -module  $M$  is *weakly extended* (from  $R$ ) provided there is a finitely generated  $R$ -module  $N$  such that  $M \mid S \otimes_R N$ . In this case we also say that  $M$  is weakly extended from  $N$ .

Our immediate goal is to show that if  $R$  has finite CM type then  $R^h$  does too. We show in Proposition 10.4 that it will suffice to show that every MCM  $R^h$ -module is weakly extended from a MCM  $R$ -module. In Lemma 10.5 we show that every finitely generated  $R^h$ -module is weakly extended. Then in Proposition 10.6 we show, assuming  $R$  has finite CM type, that MCM  $R^h$ -modules are weakly extended from MCM  $R$ -modules. The proof depends on the fact (Theorem 7.12) that rings of finite CM type have isolated singularities.

**10.4 Proposition.** *Let  $(R, \mathfrak{m}) \longrightarrow (S, \mathfrak{n})$  be a local homomorphism. Assume that every MCM  $S$ -module is weakly extended from a MCM  $R$ -module. If  $R$  has finite CM type, so has  $S$ .*

*Proof.* Let  $L_1, \dots, L_t$  be a complete list of representatives for the isomorphism classes of indecomposable MCM  $R$ -modules. Let  $L = L_1 \oplus \dots \oplus L_t$ , and put  $V = S \otimes_R L$ . Given a MCM  $S$ -module  $M$ , we choose a MCM  $R$ -module  $N$  such that  $M \mid S \otimes_R N$ . Writing  $N = L_1^{(a_1)} \oplus \dots \oplus L_t^{(a_t)}$ , we see that  $N \in \text{add}_R(L)$  and hence that  $M \in \text{add}_S(V)$ . Thus every MCM  $S$ -module is contained in  $\text{add}_S(V)$ ; now Theorem 2.2 completes the proof.  $\square$

**10.5 Lemma** ([HW09, Theorem 5.2]). *Let  $\varphi: (R, \mathfrak{m}) \longrightarrow (S, \mathfrak{n})$  be a flat local homomorphism, and assume that  $S$  is a direct limit of étale extensions of  $R$ . Then every finitely generated  $S$ -module is weakly extended from  $R$ .*

*Proof.* Let  $M$  be a finitely generated  $S$ -module, and choose a matrix  $A$  whose cokernel is  $M$ . Since all of the entries of  $A$  live in some étale extension  $T$  of  $R$ , we see that  $M = S \otimes_T N$  for some finitely generated  $T$ -module  $N$ . Refreshing notation, we may assume that  $\varphi: R \longrightarrow S$  is étale. We apply

$-\otimes_S M$  to the diagonal map  $\mu: S \otimes_R S \rightarrow S$ , getting a commutative diagram

$$(10.5.1) \quad \begin{array}{ccc} S \otimes_R S \otimes_S M & \xrightarrow{\mu \otimes 1_M} & S \otimes_S M \\ \cong \downarrow & & \downarrow \cong \\ S \otimes_R M & \longrightarrow & M \end{array}$$

in which the horizontal maps are split surjections of  $S$ -modules. The  $S$ -module structure on  $S \otimes_R M$  comes from the  $S$ -action on  $S$ , not on  $M$ . (The distinction is important; cf. Exercise 10.21.) Thus we have a split injection of  $S$ -modules  $j: M \rightarrow S \otimes_R M$ . Now write  ${}_R M$  as a directed union of finitely generated  $R$ -modules  $N_\alpha$ . The flatness of  $\varphi$  implies that  $S \otimes_R M$  is the directed union of the modules  $S \otimes_R N_\alpha$ . Since  $j(M)$  is a finitely generated  $S$ -module, there is an index  $\alpha_0$  such that  $j(M) \subseteq S \otimes_R N_{\alpha_0}$ . We put  ${}_R N = {}_R N_{\alpha_0}$ . Since  $j(M)$  is a direct summand of  $S \otimes_R M$ , it must be a direct summand of the smaller module  $S \otimes_R N$ .  $\square$

Even if we start with a MCM  $S$ -module, there is no reason to believe that the  $R$ -module  $N$  in the proof of Lemma 10.5 is MCM. The next proposition refines the lemma and will be used both here and in the next section, where we prove ascent along separable extensions of the residue field.

**10.6 Proposition.** *Let  $(R, \mathfrak{m}) \rightarrow (S, \mathfrak{n})$  be a flat local homomorphism of CM local rings. Assume that the closed fiber  $S/\mathfrak{m}S$  is Artinian and that  $S_{\mathfrak{q}}$  is Gorenstein for each prime ideal  $\mathfrak{q} \neq \mathfrak{n}$ . If every finitely generated  $S$ -module is weakly extended from  $R$ , then every MCM  $S$ -module is weakly extended from a MCM  $R$ -module. In particular, if  $R$  has finite CM type, so has  $S$ .*

*Proof.* Note that  $\dim(R) = \dim(S) =: d$  by [BH93, (A.11)]. Let  $M$  be a MCM  $S$ -module. As  $S$  is Gorenstein on the punctured spectrum, Corollary A.17

implies that  $M$  is a  $d^{\text{th}}$  syzygy of some finitely generated  $S$ -module  $U$ . We choose a finitely generated  $R$ -module  $V$  such that  $U \mid S \otimes_R V$ , say,  $U \oplus X \cong S \otimes_R V$ . Let  $W$  be a  $d^{\text{th}}$  syzygy of  $V$ . Then  $W$  is MCM by the Depth Lemma. Since  $R \rightarrow S$  is flat,  $S \otimes_R W$  is a  $d^{\text{th}}$  syzygy of  $S \otimes_R V$ , as is  $M \oplus L$ , where  $L$  is a  $d^{\text{th}}$  syzygy of  $X$ . By Schanuel's Lemma (A.9) there are finitely generated free  $S$ -modules  $G_1$  and  $G_2$  such that  $(S \otimes_R W) \oplus G_1 \cong (L \oplus M) \oplus G_2$ . Of course  $G_1$  is extended from a free  $R$ -module  $F$ . Putting  $N = W \oplus F$ , we see that  $M \mid S \otimes_R N$ . This proves the first assertion, and the second follows from Proposition 10.4.  $\square$

**10.7 Theorem.** *Let  $(R, \mathfrak{m}) \rightarrow (S, \mathfrak{n})$  be a flat local homomorphism of CM local rings. Assume that  $R$  has finite CM type and that  $S$  is the direct limit of a system  $\{(S_\alpha, \mathfrak{n}_\alpha)\}_{\alpha \in \Lambda}$  of étale extensions of  $(R, \mathfrak{m})$ . Then  $S$  has finite CM type. In particular, the Henselization  $R^h$  has finite CM type.*

*Proof.* By Lemma 10.5 and Propositions 10.4 and 10.6, it will suffice to show that  $S_{\mathfrak{q}}$  is Gorenstein for each prime ideal  $\mathfrak{q} \neq \mathfrak{n}$ .

Given an arbitrary non-maximal prime ideal  $\mathfrak{q}$  of  $S$ , put  $\mathfrak{q}_\alpha = \mathfrak{q} \cap S_\alpha$  for  $\alpha \in \Lambda$ , and let  $\mathfrak{p} = \mathfrak{q} \cap R$ . Since by Exercise 10.20  $\mathfrak{m}S_\alpha = \mathfrak{n}_\alpha$  for each  $\alpha \in \Lambda$ , we see that  $\mathfrak{m}S = \mathfrak{n}$ , and it follows that  $\mathfrak{p}$  is a non-maximal prime ideal of  $R$ . By Theorem 7.12,  $R_{\mathfrak{p}}$  is a regular local ring. Each extension  $R_{\mathfrak{p}} \rightarrow S_{\mathfrak{q}_\alpha}$  is étale by Exercise 10.20, and it follows (again from the exercise) that  $\mathfrak{p}S_{\mathfrak{q}_\alpha} = \mathfrak{q}_\alpha S_{\mathfrak{q}_\alpha}$  for each  $\alpha$ . Therefore  $\mathfrak{p}S_{\mathfrak{q}} = \mathfrak{q}S_{\mathfrak{q}}$ , so the closed fiber  $S_{\mathfrak{q}}/\mathfrak{p}S_{\mathfrak{q}}$  is a field. Since  $R_{\mathfrak{p}}$  and  $S_{\mathfrak{q}}/\mathfrak{p}S_{\mathfrak{q}}$  are Gorenstein and  $R_{\mathfrak{p}} \rightarrow S_{\mathfrak{q}}$  is flat, [BH93, (3.3.15)] implies that  $S_{\mathfrak{q}}$  is Gorenstein.  $\square$

Finally, we prove ascent of finite CM type to the completion for excel-

lent rings. Actually, a condition weaker than excellence suffices. Recall that a Noetherian ring  $A$  is *regular* provided  $A_{\mathfrak{m}}$  is a regular local ring for each maximal ideal  $\mathfrak{m}$  of  $A$ . A Noetherian ring  $A$  containing a field  $k$  is *geometrically regular over  $k$*  provided  $\ell \otimes_k A$  is a regular ring for every finite algebraic extension  $\ell$  of  $k$ . A homomorphism  $\varphi: A \rightarrow B$  of Noetherian rings is *regular* provided  $\varphi$  is flat, and for each  $\mathfrak{p} \in \text{Spec}(A)$  the fiber  $B_{\mathfrak{p}}/\mathfrak{p}B_{\mathfrak{p}}$  is geometrically regular over the field  $A_{\mathfrak{p}}/\mathfrak{p}A_{\mathfrak{p}}$ . Part of the definition of  $A$  being *excellent* is that  $A \rightarrow \widehat{A}$  is a regular homomorphism. (The other parts are that  $A$  is universally catenary and that the non-singular locus of  $B$  is open in  $\text{Spec}(B)$  for every finitely generated  $A$ -algebra  $B$ .)

We will need the following consequences of regularity of a ring homomorphism. The first assertion is clear from the definition, while the second follows from the first and from [Mat89, (32.2)].

**10.8 Proposition.** *Let  $A \rightarrow B$  be a regular homomorphism,  $\mathfrak{q} \in \text{Spec}(B)$ , and put  $\mathfrak{p} = \mathfrak{q} \cap A$ .*

(i) *The homomorphism  $A_{\mathfrak{p}} \rightarrow B_{\mathfrak{q}}$  is regular.*

(ii) *If  $A_{\mathfrak{p}}$  is a regular local ring, so is  $B_{\mathfrak{q}}$ .* □

We'll also need the following remarkable theorem due to R. Elkik (cf. [Elk73]).

**10.9 Theorem (Elkik).** *Let  $(R, \mathfrak{m})$  be a local ring and  $M$  a finitely generated  $\widehat{R}$ -module. If  $M_{\mathfrak{p}}$  is a free  $R_{\mathfrak{p}}$ -module for each non-maximal prime ideal  $\mathfrak{p}$  of  $\widehat{R}$ , then  $M$  is extended from the Henselization  $R^h$ .* □

**10.10 Corollary.** *Let  $(R, \mathfrak{m})$  be a CM local ring with  $\mathfrak{m}$ -adic completion  $\widehat{R}$ . If  $\widehat{R}$  has finite CM type, so has  $R$ . The converse holds if  $R \rightarrow \widehat{R}$  is regular, in particular if  $R$  is excellent.*

*Proof.* The first assertion is a special case of Theorem 10.1. Suppose now that  $R \rightarrow \widehat{R}$  is regular and that  $R$  has finite Cohen-Macaulay type. Let  $\mathfrak{q}$  be an arbitrary non-maximal prime ideal of  $\widehat{R}$ , and set  $\mathfrak{p} = \mathfrak{q} \cap R$ . Then  $R_{\mathfrak{p}}$  is a regular local ring by Theorem 7.12, and Proposition 10.8 implies that  $\widehat{R}_{\mathfrak{q}}$  is a regular local ring too. Thus  $\widehat{R}$  has an isolated singularity.

Now let  $M$  be an arbitrary MCM  $\widehat{R}$ -module. Then  $M_{\mathfrak{q}}$  is a free  $\widehat{R}_{\mathfrak{q}}$ -module for each non-maximal prime ideal  $\mathfrak{q}$  of  $\widehat{R}$ . By Theorem 10.9,  $M$  is extended from the Henselization, that is, there is an  $R^{\text{h}}$ -module  $N$  such that  $M \cong N \otimes_{R^{\text{h}}} \widehat{R}$ ; moreover,  $N$  is a MCM  $R^{\text{h}}$ -module by [BH93, (1.2.16) and (A.11)]. Since  $R^{\text{h}}$  has finite CM type (Theorem 10.7), Proposition 10.4 implies that  $\widehat{R}$  has finite CM type.  $\square$

It is unknown whether or not Corollary 10.10 would be true without the hypothesis that  $R$  be CM, or without the hypothesis that  $R \rightarrow \widehat{R}$  be regular. The following example from [LW00] shows, however, that we can't omit *both* hypotheses:

**10.11 Example.** Let  $T = k[[x, y, z]] / ((x^3 - y^7) \cap (y, z))$ , where  $k$  is any field. We claim that  $T$  has infinite CM type. To see this, set  $R = k[[x, y]] / (x^3 - y^7) \cong k[[t^3, t^7]]$ . Then  $R$  has infinite CM type by Theorem 4.10, since (DR2) fails for this ring. Further,  $R[[z]]$  has infinite CM type: the map  $R \rightarrow R[[z]]$  is flat with CM closed fiber, and Theorem 10.1 applies. Now  $R[[z]] \cong T / (x^3 - y^7)$ . As  $T$  and  $T / (x^3 - y^7)$  have the same dimension, every MCM  $T / (x^3 - y^7)$ -

module is MCM over  $T$ . Since  $T/(x^3 - y^7)$  has infinite CM type, the claim follows.

It is easy to check that the image of  $x$  is a non-zerodivisor in  $T$ . By [Lec86, Theorem 1],  $T$  is the completion of some local integral domain  $A$ . Then  $A$  has finite CM type; in fact, it has no MCM modules at all! For if  $A$  had a MCM module, then  $A$  would be universally catenary [Hoc73, Section 1]. But this would imply, by [Mat89, Theorem 31.7], that  $A$  is formally equidimensional, that is, all minimal primes of  $\widehat{A}$  ( $= T$ ) have the same dimension. But the two minimal primes of  $T$  obviously have dimensions two and one, contradiction.

Another example of this behavior, using a very different construction, can be found in [LW00].

### §3 Ascent along separable field extensions

Let  $(R, \mathfrak{m}, k)$  be a local ring and  $\ell/k$  a field extension. We want to lift the extension  $k \hookrightarrow \ell$  to a flat local homomorphism  $(R, \mathfrak{m}, k) \longrightarrow (S, \mathfrak{n}, \ell)$  with certain nice properties. The type of ring extension we seek is dubbed a *gonflement* by Bourbaki [Bou06, Appendice]. Translations of the term range from the innocuous “inflation” to the provocative “swelling” or “intumescence”. To avoid choosing one, we stick with the French word.

**10.12 Definition.** Let  $(R, \mathfrak{m}, k)$  be a local ring.

- (i) An *elementary gonflement* of  $R$  is either

- a) a purely transcendental extension  $R \longrightarrow (R[x])_{\mathfrak{m}[x]}$  (where  $x$  is a single indeterminate), or
  - b) an extension  $R \longrightarrow R[x]/(f)$ , where  $f$  is a monic polynomial whose reduction modulo  $\mathfrak{m}$  is irreducible in  $k[x]$ .
- (ii) A *gongflement* is an extension  $(R, \mathfrak{m}, k) \longrightarrow S$  with the following property: There is a well-ordered family  $\{R_\alpha\}_{0 \leq \alpha \leq \lambda}$  of local extensions  $(R, \mathfrak{m}, k) \hookrightarrow (R_\alpha, \mathfrak{m}_\alpha, k_\alpha)$  such that
- a)  $R_0 = R$  and  $R_\lambda = S$ ,
  - b)  $R_\beta = \bigcup_{\alpha < \beta} R_\alpha$  if  $\beta$  is a limit ordinal, and
  - c)  $R_{\beta+1}$  is an elementary gongflement of  $R_\beta$  if  $\beta \neq \lambda$ .

Elementary gongflements of type (ia) are often used to pass to a local ring with infinite residue field. (See Theorem A.22 for the reason why, and Proposition 4.4 for an application.) In this section we will need gongflements that are iterations of elementary gongflements of type (ib).

The following theorem (cf. [Bou06, Appendice, Proposition 2 and Théorème 1, pp. 39–40]) summarizes the basic properties of gongflements.

**10.13 Theorem.** *Let  $(R, \mathfrak{m}, k)$  be a local ring.*

- (i) *Let  $(R, \mathfrak{m}, k) \longrightarrow S$  be a gongflement.*
  - a)  *$S$  is local with, say, maximal ideal  $\mathfrak{n}$ . In particular,  $S$  is Noetherian.*
  - b)  *$\mathfrak{m}B = \mathfrak{n}$ .*
  - c)  *$R \longrightarrow S$  is a flat local homomorphism.*

d) With the notation as in the definition, if  $\alpha \leq \beta \leq \lambda$ , then  $R_\alpha \rightarrow R_\beta$  is a gonflement.

(ii) If  $k \rightarrow \ell$  is an arbitrary field extension, there is a gonflement  $(R, \mathfrak{m}, k) \rightarrow (S, \mathfrak{n}, \ell)$  lifting  $k \rightarrow \ell$ .

We now prove ascent of finite CM type along gonflements with separable residue field growth.

**10.14 Theorem.** *Let  $(R, \mathfrak{m}, k) \rightarrow (S, \mathfrak{n}, \ell)$  be a gonflement.*

(i) *If  $S$  has finite CM type, then  $R$  has finite CM type.*

(ii) *Assume  $R$  is CM and  $k \rightarrow \ell$  is a separable algebraic extension. If  $R$  has finite CM type, so has  $S$ .*

*Proof.* Item (i) is, again, a special case of Theorem 10.1. For the proof of (ii), we keep the notation of Definition 10.12. Each elementary gonflement  $R_\alpha \rightarrow R_{\alpha+1}$  is of type (ib). Moreover, since the induced map on residue fields is a finite separable extension, we see from Exercise 10.20 that  $R_\alpha \rightarrow R_{\alpha+1}$  is étale. By Exercise 10.18 and [BH93, A.11],  $S$  is Cohen-Macaulay and  $\dim(S) = \dim(R)$ . We will show by transfinite induction that each ring  $R_\beta$  is Gorenstein on the punctured spectrum. Theorem 7.12 says  $R$  is in fact regular on the punctured spectrum, so we have the case  $\alpha = 0$ . Now assume  $0 < \beta \leq \lambda$  and that  $R_\alpha$  is Gorenstein on the punctured spectrum for each  $\alpha < \beta$ . Let  $\mathfrak{q}_\beta$  be a non-maximal prime ideal of  $R_\beta$ , and put  $\mathfrak{q}_\alpha = \mathfrak{q}_\beta \cap R_\alpha$ , for each  $\alpha < \beta$ . In either case, whether  $\beta$  is a limit ordinal or  $\beta = \gamma + 1$  for some  $\gamma$ , the proof of Theorem 10.7 shows that  $(R_\beta)_{\mathfrak{q}_\beta}$  is Goren-

stein. Now, setting  $\beta = \lambda$ , we see that  $S$  is Gorenstein on the punctured spectrum.

By Propositions 10.4 and 10.6, we need only show that every finitely generated  $S$ -module is weakly extended from  $R$ . We shall show that, for every  $\beta \leq \lambda$ , every finitely generated  $R_\beta$ -module  $M$  is weakly extended from  $R$ . We proceed by transfinite induction again, the case  $\beta = 0$  being trivial. Suppose  $0 < \beta \leq \lambda$ . If  $\beta = \alpha + 1$  for some  $\alpha$ , then Lemma 10.5 provides a finitely generated  $R_\alpha$ -module  $N$  such that  $M \mid (R_\beta \otimes_{R_\alpha} N)$ . By induction,  $N$  is weakly extended from  $R$ , and it follows that  $M$  too is weakly extended from  $R$ . If  $\beta$  is a limit ordinal, then  $M$  is extended from  $R_\alpha$  for some  $\alpha < \beta$ , and again the inductive hypothesis shows that  $M$  is weakly extended from  $R$ .  $\square$

The separability condition in 10.14 cannot be omitted. Indeed, here is an example of a local ring  $R$  with finite CM type and an elementary gonflement  $R \rightarrow S$  such that  $S$  has infinite CM type.

**10.15 Example** ([Wie98, Example 3.4]). Let  $k$  be an imperfect field of characteristic 2, and let  $\alpha \in k - k^2$ . Put  $R = k[[x, y]]/(x^2 + \alpha y^2)$ . Then  $R$  is a one-dimensional local domain with multiplicity two, so by Theorem 4.18  $R$  has finite Cohen-Macaulay type. However, by Proposition 4.15,  $S = R \otimes_k k(\sqrt{\alpha}) = k(\sqrt{\alpha})[[x, y]]/(x + \sqrt{\alpha}y)^2$  does not have finite Cohen-Macaulay type, since it is Cohen-Macaulay but not reduced.

Recall that we did not give a self-contained proof of Theorem 4.10. Here we describe a proof, independent of the matrix decompositions in [GR78], in an important special case.

**10.16 Theorem.** *Let  $(R, \mathfrak{m}, k)$  be an analytically unramified local ring of dimension one. Assume  $R$  contains a field and that  $\text{char}(k) \neq 2, 3$  or  $5$ . Then  $R$  has finite CM type if and only if  $R$  satisfies the Drozd-Roĭter conditions (DR1) and (DR2) of Chapter 4.*

*Proof.* A complete proof of the “only if” direction is in Chapter 4. For the converse, we may assume, by Theorems 10.13 and 10.14, that  $k$  is algebraically closed. Corollary 4.17 (whose proof did not depend on Theorem 4.10!) allows us to assume that  $R$  is complete. Then  $\overline{R} = k[[t_1]] \times \cdots \times k[[t_s]]$ , where  $s \leq 3$  and the  $t_i$  are analytic indeterminates. An elementary but tedious computation (cf. [Yos90, pages 72–73]) now shows that  $R$  is a finite birational extension of an ADE singularity  $A$ . Since  $A$  has finite CM type (Corollary 8.19), Proposition 4.14 implies that  $R$  has finite CM type too.  $\square$

## §4 Equicharacteristic Gorenstein singularities

We now assemble the pieces and obtain a nice characterization of the equicharacteristic Gorenstein singularities of finite CM type.

**10.17 Corollary.** *Let  $(R, \mathfrak{m}, k)$  be an excellent, Gorenstein ring containing a field of characteristic different from 2, 3, 5, and let  $K$  be an algebraic closure of  $k$ . Assume  $d = \dim(R) \geq 1$  and that  $k$  is perfect. Then  $R$  has finite CM type if and only if there is a non-zero non-unit  $f \in k[[x_0, \dots, x_d]]$  such that*

$\widehat{R} \cong k[[x_0, \dots, x_d]]/(f)$  and  $K[[x_0, \dots, x_d]]/(f)$  is a complete ADE hypersurface singularity (cf. Chapter 9).

*Proof.* Using [Mat89, Theorem 22.5], we see that  $K[[x_0, \dots, x_d]]/(f)$  is flat over  $k[[x_0, \dots, x_d]]/(f)$  for any non-unit  $f \in k[[x_0, \dots, x_d]]$ . The “if” direction now follows from Theorem 10.1 and the fact (cf. Theorem 9.8) that simple singularities have finite CM type.

For the converse, suppose  $R$  has finite CM type. Since  $R$  is CM and excellent, the completion  $\widehat{R}$  has finite CM type by Corollary 10.10. Moreover, Theorem 9.15 implies, since  $R$  is Gorenstein, that  $\widehat{R}$  is a hypersurface, that is,  $\widehat{R} \cong k[[x_0, \dots, x_d]]/(f)$  for some non-zero non-unit  $f$ .

We next pass to the ring  $A = K \otimes_k \widehat{R}$ , which we claim is a direct limit of finite étale extensions of  $\widehat{R}$ . To see this, write  $K = \bigcup_{\alpha \in \Lambda} F_\alpha$ , where each  $F_\alpha$  is a finite extension of  $k$ . For each  $\alpha \in \Lambda$ , the field extension  $k \rightarrow F_\alpha$  is unramified (since  $F_\alpha$  is separable over  $k$ ), and it follows easily that  $\widehat{R} \rightarrow F_\alpha \otimes_k \widehat{R}$  is unramified as well. Since each  $F_\alpha \otimes_k \widehat{R}$  is a finitely generated free  $\widehat{R}$ -module and  $K \otimes_k \widehat{R} = \bigcup_{\alpha} (F_\alpha \otimes_k \widehat{R})$ , the claim follows.

Since  $\widehat{R}$  is excellent (being complete) and since  $A$  is a direct limit of étale extensions of  $\widehat{R}$ , a theorem of S. Greco [Gre76, Theorem 5.3] implies that  $A$  is excellent. Since  $K$  is a gonflement of  $k$ , Exercise 10.22 implies that  $A$  is a gonflement of  $\widehat{R}$ , and that  $K$  is a coefficient field for  $A$ . Therefore  $A$  has finite CM type, by Theorem 10.14.

Now  $A = T/(f)$ , where  $T = K \otimes_k k[[x_0, \dots, x_d]] = \bigcup_{\alpha} F_\alpha[[x_0, \dots, x_d]]$ , where, as before, the  $F_\alpha$  are finite extensions of  $k$  contained in  $K$ . Clearly  $\widehat{T} = K[[x_0, \dots, x_d]]$ , so  $\widehat{A} = K[[x_0, \dots, x_d]]/(f)$ . By Corollary 10.10, we see that  $\widehat{A}$  has finite CM type. Therefore, by Theorem 9.8  $K[[x_0, \dots, x_d]]/(f) = \widehat{A}$  is a

complete ADE hypersurface singularity. □

## §5 Exercises

**10.18 Exercise.** Let  $(R, \mathfrak{m}, k) \rightarrow (S, \mathfrak{n}, \ell)$  be a flat local homomorphism, and let  $M$  be a finitely generated  $R$ -module. Prove that  $S \otimes_R M$  is a MCM  $S$ -module if and only if  $M$  is MCM and the closed fiber  $S/\mathfrak{m}S$  is a CM ring. (Cf. [BH93, (1.2.16) and (A.11)].)

**10.19 Exercise.** Let  $(R, \mathfrak{m}) \rightarrow (S, \mathfrak{n})$  be a flat local homomorphism. Prove that the following two conditions are equivalent:

- (i) The induced map  $R/\mathfrak{m} \rightarrow S/\mathfrak{m}S$  is an isomorphism.
- (ii) The induced map  $R/\mathfrak{m} \rightarrow S/\mathfrak{n}$  is an isomorphism and  $\mathfrak{m}S = \mathfrak{n}$ .

**10.20 Exercise.** Let  $\varphi: (R, \mathfrak{m}) \rightarrow (S, \mathfrak{n})$  be a flat local homomorphism that is essentially of finite type (that is,  $S$  is a localization of a finitely generated  $R$ -algebra).

- (i) Prove that  $S/\mathfrak{m}S$  is Artinian.
- (ii) Prove that  $R \rightarrow S$  is unramified if and only if
  - a)  $\mathfrak{m}S = \mathfrak{n}$ , and
  - b)  $S/\mathfrak{n}$  is a finite, separable field extension of  $R/\mathfrak{m}$ .
- (iii) Let  $\mathfrak{q}$  be a prime ideal of  $S$ , and put  $\mathfrak{p} = \varphi^{-1}(\mathfrak{q})$ . If  $R \rightarrow S$  is unramified, prove that  $R_{\mathfrak{p}} \rightarrow S_{\mathfrak{q}}$  is unramified.

**10.21 Exercise.** Find an example of an étale local homomorphism  $R \rightarrow S$  and a finitely generated  $S$ -module  $M$  such that the two  $S$ -actions on  $S \otimes_R M$  (one via the action on  $S$ , the other via the action on  $M$ ) give non-isomorphic  $S$ -modules.

**10.22 Exercise.** Let  $(R, \mathfrak{m})$  be a local ring with a coefficient field  $k$ , and let  $K/k$  be an algebraic field extension. Prove that  $K \otimes_k R$  is a gonflement of  $R$  and that  $K$  is a coefficient field for  $R$ . (First do the case where  $k \rightarrow K$  is an elementary gonflement of type (ib) in Definition 10.12.)

**10.23 Exercise.** Let  $(R, \mathfrak{m}, k)$  be a one-dimensional local ring satisfying the Drozd-Roïter conditions (DR1) and (DR2) of Chapter 4, and let  $R \rightarrow (S, \mathfrak{n}, \ell)$  be a gonflement. Prove, without reference to finite CM type, that  $S$  satisfies (DR1) and (DR2).

## *Auslander-Buchweitz theory*

As we saw back in Chapter 3, trying to understand the whole category of finitely generated modules over a local ring is impractical, so we restrict to maximal Cohen-Macaulay modules. In fact, this is not as restrictive as it seems at first: any finitely generated module over a CM local ring with canonical module can be approximated by a MCM module, in a precise sense due originally to Auslander and Buchweitz [AB89]. The theory as originally constructed in [AB89] is quite abstract, and has since been further generalized. In keeping with our general strategy, we adopt a stubbornly concrete point of view. We deal exclusively with CM local rings, finitely generated modules, and approximations by MCM modules. We also use the more limited terminology of *MCM approximations* and *FID hulls*, rather than the general notions of (pre)covers and (pre)envelopes.

In the first section we recall some basics on finitely generated modules of finite injective dimension, and particularly canonical modules, which occupy the central spot in the theory. We then detail the theory of MCM approximations and FID hulls, following Auslander and Buchweitz's original construction. Finally, we give some applications in terms of Auslander's  $\delta$ -invariant. Other applications will appear in later chapters.

### **§1 Canonical modules**

Here we give a quick primer on finitely generated modules of finite injective dimension over local rings and the most distinguished of such modules, the

canonical module.

We point out first that over CM local rings, finitely generated modules of finite injective dimension exist.

**11.1 Proposition.** *Let  $(R, \mathfrak{m}, k)$  be a CM local ring. Then  $R$  admits a non-zero finitely generated module of finite injective dimension.*

*Proof.* Let  $\mathbf{x}$  be a system of parameters for  $R$  and  $\bar{R}$  the quotient  $R/(\mathbf{x})$ . The injective hull  $E = E_{\bar{R}}(k)$  of the residue field of  $\bar{R}$  has finite length over  $\bar{R}$  and hence over  $R$ . It follows that  $M = \text{Hom}_R(\bar{R}, E)$  is finitely generated over  $R$ , and dualizing the Koszul resolution of  $\bar{R}$  into  $E$  displays  $\text{injdim } M < \infty$ .  $\square$

As an aside, we should point out here the conjecture of H. Bass [Bas63] that the converse holds as well: “It seems conceivable that, say for  $A$  local, there exist finitely generated  $M \neq 0$  with finite injective dimension only if  $A$  is a Cohen-Macaulay ring.” This conjecture was established for local rings of prime characteristic or essentially of finite type over a field of characteristic zero by C. Peskine and L. Szpiro [PS73] using their Intersection Theorem. Since P. Roberts has proved the Intersection Theorem for all local rings [Rob87], Bass’ Conjecture holds in general.

The first hint of a connection between modules of finite injective dimension and MCM modules comes in the next result, due to Ischebeck [Isch69], and its consequence below. We omit the proofs.

**11.2 Theorem.** *Let  $(R, \mathfrak{m}, k)$  be a local ring and  $M, N$  non-zero finitely generated  $R$ -modules with  $\text{injdim}_R N < \infty$ . Then*

$$\text{depth } R - \text{depth } M = \sup \left\{ i \mid \text{Ext}_R^i(M, N) \neq 0 \right\}.$$

**11.3 Proposition.** *Let  $(R, \mathfrak{m}, k)$  be a CM local ring and  $M, N$  non-zero finitely generated  $R$ -modules. Then*

- (i)  *$M$  is MCM if and only if  $\text{Ext}_R^i(M, Y) = 0$  for all  $i > 0$  and all finitely generated  $R$ -modules  $Y$  of finite injective dimension, and*
- (ii)  *$N$  has finite injective dimension if and only if  $\text{Ext}_R^i(X, N) = 0$  for all  $i > 0$  and all MCM  $R$ -modules  $X$ .*

Colloquially, we interpret Prop. 11.3 as the statement that MCM modules and finitely generated modules of finite injective dimension are “orthogonal.” It will transpire that the intersection is “spanned” by a single module, namely the canonical module, to which we now turn. See [BH93, Chapter 3] for the details we omit.

**11.4 Definition.** Let  $(R, \mathfrak{m}, k)$  be a CM local ring of dimension  $d$ . A finitely generated  $R$ -module  $\omega$  is a *canonical module* for  $R$  if  $\omega$  is MCM, has finite injective dimension, and satisfies  $\dim_k \text{Ext}_R^d(k, \omega) = 1$ .

The condition on  $\text{Ext}_R^d(k, \omega)$  is a sort of rank-one normalizing assumption: taking into account the calculation of both depth and injective dimension in terms of  $\text{Ext}_R^i(k, -)$ , we can write Definition 11.4 compactly as

$$\text{Ext}_R^i(k, \omega) \cong \begin{cases} k & \text{if } i = \dim R, \text{ and} \\ 0 & \text{otherwise.} \end{cases}$$

We need a laundry list of properties of canonical modules. Define the *codepth* of an  $R$ -module  $M$  to be  $\text{depth} R - \text{depth} M$ .

**11.5 Theorem.** *Let  $(R, \mathfrak{m}, k)$  be a CM local ring and  $\omega$  a canonical module for  $R$ . Then*

(i)  *$\omega$  is unique up to isomorphism, and  $R$  is Gorenstein if and only if  $\omega \cong R$ ;*

(ii)  *$\text{End}_R(\omega) \cong R$ .*

(iii) *Let  $M$  be a CM  $R$ -module of codepth  $t$ , and set  $M^\vee = \text{Ext}_R^t(M, \omega)$ .*

*Then*

(a)  *$M^\vee$  is also CM of codepth  $t$ ;*

(b)  *$\text{Ext}_R^i(M, \omega) = 0$  for  $i \neq t$ ; and*

(c)  *$M^{\vee\vee}$  is naturally isomorphic to  $M$ .*

(iv) *The canonical module behaves well with respect to factoring out a regular sequence, completion, and localization.*

It is a result of Sharp, Foxby, and Reiten [Sha71, Fox72, Rei72] that a CM local ring  $R$  has a canonical module if and only if  $R$  is a homomorphic image of a Gorenstein local ring.

The stipulation that  $\text{Ext}_R^{\dim R}(k, \omega_R) \cong k$  is, as we observed, a kind of rank-one condition. Indeed, under a mild additional condition it forces  $\omega_R$  to be isomorphic to an ideal of  $R$ . We say that  $R$  is *generically Gorenstein* if  $R_{\mathfrak{p}}$  is Gorenstein for each minimal prime  $\mathfrak{p}$  of  $R$ .

**11.6 Proposition.** *Let  $R$  be a CM local ring and  $\omega$  a canonical module for  $R$ . If  $R$  is generically Gorenstein, then  $\omega$  is isomorphic to an ideal of  $R$ , and conversely. In this case,  $\omega$  is an ideal of pure height one (that is,*

every associated prime of  $\omega$  has height one), and  $R/\omega$  is a Gorenstein ring of dimension  $\dim R - 1$ .

*Proof.* As  $R_{\mathfrak{p}}$  is Gorenstein for every minimal  $\mathfrak{p}$ , we conclude that  $\omega_{\mathfrak{p}}$  is free of rank one for those primes. In particular if we denote by  $K$  the total quotient ring, obtained by inverting the complement of the union of those minimal primes, then  $\omega \otimes_R K$  is a rank-one projective module over the semilocal ring  $K$ . Thus  $\omega \otimes_R K \cong K$ . Fixing an isomorphism and composing with the natural map gives an  $R$ -homomorphism  $\omega \rightarrow K$ , which is injective as  $\omega$  is torsion-free. Multiplying the image by a carefully chosen non-zero-divisor clears the denominators and knocks the image down into  $R$ , where it is an ideal. Being locally free at the minimal primes, it has height at least one.

Since  $\omega$  is MCM, the short exact sequence

$$0 \rightarrow \omega \rightarrow R \rightarrow R/\omega \rightarrow 0$$

forces  $\text{depth}(R/\omega) \geq \dim R - 1$ , and since  $\text{height } \omega \geq 1$  we have  $\dim R/\omega \leq \dim R - 1$ . Thus  $R/\omega$  is a CM ring, in particular, unmixed, so  $\omega$  has pure height one. Furthermore,  $R/\omega$  is a CM  $R$ -module of codepth 1. Applying  $\text{Hom}_R(-, \omega)$  thus gives an exact sequence

$$\text{Hom}_R(R/\omega, \omega) \rightarrow \omega \rightarrow R \rightarrow \text{Ext}_R^1(R/\omega, \omega) \rightarrow 0$$

and  $\text{Ext}_R^1(R/\omega, \omega) = (R/\omega)^\vee$  is the canonical module for  $R/\omega$  by the discussion after Theorem 11.5. Since  $R/\omega$  is torsion and  $\omega$  is torsion-free, the leftmost term in the exact sequence vanishes, whence  $(R/\omega)^\vee$  is isomorphic to  $R/\omega$  itself, so  $R/\omega$  is Gorenstein.

For the converse, assume that  $\omega$  is embedded into  $R$  as an ideal. Then as before we see that  $\text{height } \omega \geq 1$ , so  $\omega$  is not contained in any minimal prime and  $R_{\mathfrak{p}}$  is Gorenstein for every minimal  $\mathfrak{p}$ .  $\square$

We quickly observe, using this result, that there does indeed exist a CM local ring which is not a homomorphic image of a Gorenstein local ring, and hence does not admit a canonical module. This was first constructed by Ferrand and Raynaud [FR70]. Specifically, they construct a one-dimensional local domain  $(R, \mathfrak{m})$  such that the completion  $\widehat{R}$  is not generically Gorenstein. If  $R$  were to have a canonical module  $\omega_R$ , it would be embeddable as an  $\mathfrak{m}$ -primary ideal of  $R$ . The completion  $\widehat{\omega_R}$  is then a canonical module for  $\widehat{R}$ , and is an ideal of  $\widehat{R}$ . But this contradicts the criterion above.

We finish the section with the promised identification of the intersection of the class of MCM modules with that of modules of finite injective dimension.

**11.7 Proposition.** *Let  $R$  be a CM local ring with canonical module  $\omega$  and let  $M$  be a finitely generated  $R$ -module. If  $M$  is both MCM and of finite injective dimension, then  $M$  is isomorphic to a direct sum of copies of  $\omega$ .*

*Proof.* Let  $F$  be a free module mapping onto the dual  $M^\vee = \text{Hom}_R(M, \omega)$  with kernel  $K$ . Dualizing gives a short exact sequence

$$0 \longrightarrow M \longrightarrow F^\vee \longrightarrow K^\vee \longrightarrow 0$$

where  $K^\vee$  is MCM as  $K$  is. Proposition 11.3(ii) implies that the sequence splits as  $\text{injdim}_R M < \infty$ , making  $M$  a direct summand of  $F^\vee$ . Dualizing again displays  $M^\vee$  as a direct summand of the free module  $F \cong F^{\vee\vee}$ , whence  $M^\vee$  is free and  $M$  is a direct sum of copies of  $\omega$ .  $\square$

If  $R$  is not assumed to have a canonical module, the MCM modules of finite injective dimension are called *Gorenstein modules*. Should any exist, there is one of minimal rank and all others are direct sums of copies of the minimal one. See Corollary A.17 for an application of Gorenstein modules.

## §2 MCM approximations and FID hulls

Throughout this section,  $(R, \mathfrak{m}, k)$  denotes a CM local ring with canonical module  $\omega$ .

Propositions 11.3 and 11.7 suggest that we view the MCM modules and modules of finite injective dimension over  $R$  as orthogonal subspaces of the space of all finitely generated modules, with intersection spanned by the canonical module  $\omega$ . Guided by this intuition and memories of basic linear algebra, we expect to be able to project any  $R$ -module onto these subspaces.

**11.8 Definition.** Let  $M$  be a non-zero finitely generated  $R$ -module. An exact sequence of finitely generated  $R$ -modules

$$0 \longrightarrow Y \longrightarrow X \longrightarrow M \longrightarrow 0$$

is a *MCM approximation* of  $M$  if  $X$  is MCM and  $\text{injdim}_R Y < \infty$ . Dually, an exact sequence

$$0 \longrightarrow M \longrightarrow Y' \longrightarrow X' \longrightarrow 0$$

is a *hull of finite injective dimension* or *FID hull* if  $\text{injdim} Y' < \infty$  and either  $X'$  is MCM or  $X' = 0$ .

We sometimes abuse language and refer to the modules  $X$  and  $Y'$  as the MCM approximation and FID hull of  $M$ , rather than the whole extensions.

The orthogonality relations between MCM modules and modules of finite injective dimension translate into lifting properties for the MCM approximations and FID hulls.

**11.9 Proposition.** *Let  $0 \rightarrow Y \rightarrow X \rightarrow M \rightarrow 0$  be a MCM approximation of  $M$  and let  $\varphi: Z \rightarrow M$  be a homomorphism with  $Z$  MCM. Then  $\varphi$  factors through  $X$ . Any two liftings of  $\varphi$  are homotopic, i.e. their difference factors through  $Y$ .*

*Proof.* Applying  $\text{Hom}_R(Z, -)$  to the approximation gives the exact sequence

$$0 \rightarrow \text{Hom}_R(Z, Y) \rightarrow \text{Hom}_R(Z, X) \rightarrow \text{Hom}_R(Z, M) \rightarrow \text{Ext}_R^1(Z, Y),$$

the rightmost term of which vanishes by Proposition 11.3(ii). Thus  $\varphi \in \text{Hom}_R(Z, M)$  lifts to an element of  $\text{Hom}_R(Z, X)$ . The final assertion follows as well from exactness.  $\square$

We leave it as an exercise for the reader to state and prove the dual statement for FID hulls.

The lifting property of Proposition 11.9 allows a Schanuel-type result: if  $0 \rightarrow Y_1 \rightarrow X_1 \rightarrow M \rightarrow 0$  and  $0 \rightarrow Y_2 \rightarrow X_2 \rightarrow M \rightarrow 0$  are two MCM approximations of the same module  $M$ , then  $X_1 \oplus Y_2 \cong X_2 \oplus Y_1$ . We leave the details to the reader. (One can also proceed directly, via the orthogonality relation  $\text{Ext}_R^1(X_i, Y_j) = 0$ ; compare with Lemma A.9.) Just as for free resolutions, this motivates a notion of minimality for MCM approximations.

**11.10 Definition.** Let  $s: 0 \rightarrow Y \xrightarrow{i} X \xrightarrow{p} M \rightarrow 0$  be a MCM approximation of a non-zero finitely generated  $R$ -module  $M$ . We say that  $s$  is *minimal* provided  $Y$  and  $X$  have no non-zero direct summand in common via  $i$ . In

other words, for any direct-sum decomposition  $X = X_0 \oplus X_1$  with  $X_0 \subseteq \text{im } i$ , we must have  $X_0 = 0$ .

Observe that any common direct summand of  $Y$  and  $X$  is both MCM and of finite injective dimension, so by Proposition 11.7 is a direct sum of copies of the canonical module  $\omega$ .

While the definition of minimality above is quite natural, in practice a more technical notion is useful.

**11.11 Definition.** Let  $s: 0 \rightarrow Y \xrightarrow{i} X \xrightarrow{p} M \rightarrow 0$  be a MCM approximation of a non-zero finitely generated  $R$ -module  $M$ . We say that  $s$  is *right minimal* if whenever  $\varphi: X \rightarrow X$  is an endomorphism such that  $p\varphi = p$ , in fact  $\varphi$  is an automorphism.

The equivalence of minimality and right minimality is “well-known to experts”; the proof we give here is due to M. Hashimoto and A. Shida [HS97] (see also [Yos93]). It turns out that passing to the completion is essential to the argument.

**11.12 Lemma.** Let  $s: 0 \rightarrow Y \xrightarrow{i} X \xrightarrow{p} M \rightarrow 0$  be a MCM approximation of a non-zero  $R$ -module  $M$ . Let  $\widehat{s}: 0 \rightarrow \widehat{Y} \xrightarrow{\widehat{i}} \widehat{X} \xrightarrow{\widehat{p}} \widehat{M} \rightarrow 0$  be the completion of  $s$ . Then  $\widehat{s}$  is a MCM approximation of  $\widehat{M}$ , and the following are equivalent.

- (i)  $\widehat{s}$  is right minimal;
- (ii)  $s$  is right minimal;
- (iii)  $s$  is minimal;

(iv)  $\hat{s}$  is minimal.

*Proof.* That  $\hat{s}$  is a MCM approximation of  $\widehat{M}$  is trivial; the real matter is the equivalence.

(i)  $\implies$  (ii) Assume that  $\hat{s}$  is right minimal, and  $\varphi \in \text{End}_R(X)$  satisfies  $p\varphi = p$ . Then  $\widehat{p}\widehat{\varphi} = \widehat{p}$ , so  $\widehat{\varphi}$  is an automorphism by hypothesis, whence  $\varphi$  is an automorphism as well.

(ii)  $\implies$  (iii) If  $X = X_0 \oplus X_1$  is a direct sum decomposition of  $X$  with  $X_0 \subseteq \text{im } i$ , then the idempotent  $\varphi: X \rightarrow X \hookrightarrow X$  obtained from the projection onto  $X_0$  satisfies  $p\varphi = p$ . Thus  $X_0 \neq 0$  implies that  $s$  is not right minimal.

(iii)  $\implies$  (iv) Assume that  $\hat{s}$  is not minimal, so that  $\widehat{Y}$  and  $\widehat{X}$  have a common non-zero direct summand via  $i$ . We have already observed that such a direct summand must be a direct sum of copies of the canonical module  $\widehat{\omega}$ , so there exist homomorphisms  $\sigma: \widehat{X} \rightarrow \widehat{\omega}$  and  $\tau: \widehat{\omega} \rightarrow \widehat{Y}$  such that

$$\sigma \widehat{i} \tau: \widehat{\omega} \rightarrow \widehat{Y} \rightarrow \widehat{X} \rightarrow \widehat{\omega}$$

is the identity on  $\widehat{\omega}$ . Write  $\sigma = \sum_j a_j \widehat{\sigma}_j$  and  $\tau = \sum_k b_k \widehat{\tau}_k$ , where  $\sigma_j \in \text{Hom}_R(X, \omega)$ ,  $\tau_k \in \text{Hom}_R(\omega, Y)$ , and  $a_j, b_k \in \widehat{R}$ . Then

$$\sum_{j,k} a_j b_k \widehat{\sigma}_j \widehat{i} \widehat{\tau}_k = 1 \in \text{End}_{\widehat{R}}(\widehat{\omega}) \cong \widehat{R}.$$

Since  $\widehat{R}$  is local, at least one of the summands  $a_j b_k \widehat{\sigma}_j \widehat{i} \widehat{\tau}_k$  is a unit of  $\widehat{R}$ . It follows that  $\sigma_j \widehat{i} \tau_k$  is a unit of  $R$ , that is,  $\sigma_k \widehat{i} \tau_k: \omega \rightarrow \omega$  is an isomorphism. Thus  $s$  is not minimal.

(iv)  $\implies$  (i) We assume that  $R = \widehat{R}$  is complete. Let  $\varphi: X \rightarrow X$  be a non-isomorphism satisfying  $p\varphi = p$ . Let  $\Lambda \subset \text{End}_R(X)$  be the subring generated

by  $R$  and  $\varphi$ , and observe that  $\Lambda$  is commutative and is a finitely generated  $R$ -module.

As  $\varphi$  carries the kernel of  $p$  into itself,  $s$  is naturally a short exact sequence of (finitely generated)  $\Lambda$ -modules. In particular, multiplication by  $\varphi \in \Lambda$  is the identity on the non-zero module  $M$ , so by NAK  $\varphi$  is not contained in the radical of  $\Lambda$ . On the other hand,  $\varphi$  is not an isomorphism on  $X$ , so is not a unit of  $\Lambda$ . Thus  $\Lambda$  is not an nc-local ring. Since  $R$  is Henselian, it follows that  $\Lambda$  contains a non-trivial idempotent  $e \neq 0, 1$ .

Now  $\varphi \in R + (1 - \varphi)\Lambda$ , so  $R + (1 - \varphi)\Lambda = \Lambda$ . In particular,  $\bar{\Lambda} := \Lambda/(1 - \varphi)\Lambda$  is a quotient of  $R$ , so is a local ring. Replacing  $e$  by  $1 - e$  if necessary, we may assume that  $\bar{e} = \bar{1}$  in  $\bar{\Lambda}$ . Since  $\varphi$  acts as the identity on  $M$ , we see that  $M$  is naturally a  $\bar{\Lambda}$ -module, and in particular  $e$  also acts as the identity on  $M$ .

Set  $X_0 = \text{im}(1 - e) = \ker(e) \subseteq X$ . Then  $X_0$  is a non-zero direct summand of  $X$ , and  $p(X_0) = 0$  since  $e$  acts trivially on  $M$ . Thus  $s$  is not minimal.  $\square$

**11.13 Proposition.** *If a finitely generated module  $M$  admits a MCM approximation, then there is a minimal one, which moreover is unique up to isomorphism of exact sequences inducing the identity on  $M$ .*

*Proof.* Removing any direct summands common to  $Y$  and  $X$  via  $i$  in a given MCM approximation of  $M$ , we arrive at a minimal one. For uniqueness, suppose we have two minimal approximations  $s: 0 \rightarrow Y \xrightarrow{i} X \xrightarrow{p} M \rightarrow 0$  and  $s': 0 \rightarrow Y' \xrightarrow{i'} X' \xrightarrow{p'} M \rightarrow 0$ . The lifting property delivers a commu-

tative diagram with exact rows

$$\begin{array}{ccccccccc}
 0 & \longrightarrow & Y & \xrightarrow{i} & X & \xrightarrow{p} & M & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow \alpha & & \parallel & & \\
 0 & \longrightarrow & Y' & \xrightarrow{i'} & X' & \xrightarrow{p'} & M & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow \beta & & \parallel & & \\
 0 & \longrightarrow & Y & \xrightarrow{i} & X & \xrightarrow{p} & M & \longrightarrow & 0
 \end{array}$$

in which, in particular,  $p\beta\alpha = p$ . Since minimality implies right minimality,  $\beta\alpha$  is an isomorphism. A similar diagram shows that  $\alpha\beta$  is an isomorphism as well, so that  $s$  and  $s'$  are isomorphic exact sequences via an isomorphism which is the identity on  $M$ . □

Here is yet a third notion of minimality for MCM approximations, introduced by Hashimoto and Shida [HS97] and used to good effect by Simon and Strooker [SS02]. Set  $d = \dim R$ . It's immediate from the definition that a MCM approximation  $0 \rightarrow Y \rightarrow X \rightarrow M \rightarrow 0$  induces isomorphisms

$$\text{Ext}_R^i(k, M) \cong \begin{cases} \text{Ext}_R^{i+1}(k, Y) & \text{for } 0 \leq i \leq d - 2 \text{ and} \\ \text{Ext}_R^i(k, X) & \text{for } i \geq d + 1, \end{cases}$$

and a 4-term exact sequence

$$0 \longrightarrow \text{Ext}_R^{d-1}(k, M) \longrightarrow \text{Ext}_R^d(k, Y) \longrightarrow \text{Ext}_R^d(k, X) \longrightarrow \text{Ext}_R^d(k, M) \longrightarrow 0.$$

We will call the approximation *Ext-minimal* if the induced map of  $k$ -vector spaces  $\text{Ext}_R^d(k, Y) \rightarrow \text{Ext}_R^d(k, X)$  in the middle of this exact sequence is the zero map. Equivalently, one (and hence both) of the natural maps  $\text{Ext}_R^{d-1}(k, M) \rightarrow \text{Ext}_R^d(k, Y)$  and  $\text{Ext}_R^d(k, X) \rightarrow \text{Ext}_R^d(k, M)$  is an isomorphism. This means in particular that the Bass numbers of  $M$  are completely determined by  $X$  and  $Y$ .

If in a MCM approximation of  $M$  there is a non-zero indecomposable direct summand of  $Y$  carried isomorphically to a summand of  $X$ , then we've already seen that the summand must be isomorphic to  $\omega$ , and so  $\text{Ext}_R^d(k, Y) \rightarrow \text{Ext}_R^d(k, X)$  has as a summand the identity map on  $k = \text{Ext}_R^d(k, \omega)$ . Thus Ext-minimality implies minimality as defined above. In fact, all three notions of minimality are equivalent. As the proof of this fact uses some local cohomology, we relegate it to the Exercises.

**11.14 Proposition.** *Let  $(R, \mathfrak{m})$  be a CM local ring with canonical module, and let  $M$  be a non-zero finitely generated  $R$ -module. For a given MCM approximation of  $M$ , minimality, right minimality, and Ext-minimality are equivalent.*  $\square$

The considerations above are exactly paralleled on the FID hull side. A FID hull  $0 \rightarrow M \xrightarrow{j} Y \xrightarrow{q} X \rightarrow 0$  is *minimal* if  $Y$  and  $X$  have no non-zero direct summand in common via  $q$ , is *left minimal* if every endomorphism  $\psi \in \text{End}_R(Y)$  such that  $\psi j = j$  is in fact an automorphism, and is *Ext-minimal* if the induced linear map  $\text{Ext}_R^d(k, Y) \rightarrow \text{Ext}_R^d(k, X)$  is zero. The three notions are equivalent by arguments exactly similar to those above.

We turn now to existence. The construction of MCM approximations is most transparent when the approximated module is CM, so we state that case separately. In particular, the construction below applies when  $M$  is an  $R$ -module of finite length, for example  $M = R/\mathfrak{m}^n$  for some  $n \geq 1$ . We will return to this example in §4.

**11.15 Proposition.** *Let  $(R, \mathfrak{m})$  be a CM local ring with canonical module  $\omega$ , and let  $M$  be a CM  $R$ -module. Then  $M$  has a minimal MCM approximation.*

*Proof.* Let  $t = \text{codepth} M$ . By Theorem 11.5,  $M^\vee = \text{Ext}_R^t(M, \omega)$  is again CM of codepth  $t$ . In a truncated minimal free resolution of  $M^\vee$

$$0 \longrightarrow \text{syz}_t^R(M^\vee) \longrightarrow F_{t-1} \longrightarrow \cdots \longrightarrow F_1 \longrightarrow F_0 \longrightarrow M^\vee \longrightarrow 0$$

the  $t^{\text{th}}$  syzygy  $\text{syz}_t^R(M^\vee)$  is MCM. Apply  $\text{Hom}_R(-, \omega)$  to get a complex

$$0 \longrightarrow F_0^\vee \longrightarrow F_1^\vee \longrightarrow \cdots \longrightarrow F_{t-1}^\vee \longrightarrow \text{syz}_t^R(M^\vee)^\vee \longrightarrow 0$$

with homology  $\text{Ext}_R^i(M^\vee, \omega)$ , which is  $M^{\vee\vee} \cong M$  for  $i = t$  and trivial otherwise. Inserting the homology at the rightmost end, and defining  $K$  to be the kernel, we get a short exact sequence

$$(11.15.1) \quad 0 \longrightarrow K \longrightarrow \text{syz}_t^R(M^\vee)^\vee \longrightarrow M \longrightarrow 0,$$

in which the middle term is MCM. Since  $K$  has a finite resolution by direct sums of copies of  $R^\vee = \omega$ , it has finite injective dimension, so that (11.15.1) is a MCM approximation of  $M$ .

It is easy to see that our initial choice of a minimal resolution forces the obtained approximation to be minimal as well.  $\square$

For the general case, we give an independent construction of a MCM approximation of a finitely generated module, which simultaneously produces an FID hull as well. This argument is essentially that of [AB89], though in a more concrete setting. There are two other constructions: the *pitchfork construction*, originally due also to Auslander and Buchweitz, and the *gluing construction* of Herzog and Martsinkovsky [HM93].

**11.16 Theorem.** *Let  $(R, \mathfrak{m}, k)$  be a CM local ring with canonical module  $\omega$ , and let  $M$  be a finitely generated  $R$ -module. Then  $M$  admits a MCM approximation and a FID hull.*

*Proof.* We construct the approximation and hull by induction on codepth  $M$ . When  $M$  is MCM itself, the MCM approximation is trivial. For a FID hull, take a free module  $F$  mapping onto the dual  $M^\vee = \text{Hom}_R(M, \omega)$  as in the proof of Proposition 11.15. In the short exact sequence

$$0 \longrightarrow \text{syz}_1^R(M^\vee) \longrightarrow F \longrightarrow M^\vee \longrightarrow 0,$$

the syzygy module  $\text{syz}_1^R(M^\vee)$  is again MCM, so applying  $\text{Hom}_R(-, \omega)$  gives another exact sequence

$$0 \longrightarrow M \longrightarrow F^\vee \longrightarrow \text{syz}_1^R(M^\vee)^\vee \longrightarrow 0$$

in which  $F^\vee \cong \omega^{(n)}$  has finite injective dimension and  $\text{syz}_1^R(M^\vee)^\vee$  is MCM.

Suppose now that codepth  $M = t \geq 1$ . Taking a syzygy of  $M$  in a minimal free resolution

$$0 \longrightarrow \text{syz}_1^R(M) \longrightarrow F \longrightarrow M \longrightarrow 0$$

we have by induction a FID hull of  $\text{syz}_1^R(M)$

$$0 \longrightarrow \text{syz}_1^R(M) \longrightarrow Y' \longrightarrow X' \longrightarrow 0.$$

Construct the pushout diagram from these two sequences.

$$\begin{array}{ccccccc}
 & & 0 & & 0 & & \\
 & & \downarrow & & \downarrow & & \\
 0 & \longrightarrow & \text{syz}_1^R(M) & \longrightarrow & F & \longrightarrow & M \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \parallel \\
 0 & \longrightarrow & Y' & \longrightarrow & W & \longrightarrow & M \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \\
 & & X' & \xlongequal{\quad} & X' & & \\
 & & \downarrow & & \downarrow & & \\
 & & 0 & & 0 & & 
 \end{array}$$

As  $X'$  is MCM and  $F$  is free, the exact middle column forces  $W$  to be MCM, so that the middle row is a MCM approximation of  $M$ .

A FID hull for  $W$  exists by the base case of the induction:

$$0 \longrightarrow W \longrightarrow Y'' \longrightarrow X'' \longrightarrow 0$$

and constructing another pushout

$$\begin{array}{ccccccc}
 & & 0 & & 0 & & \\
 & & \downarrow & & \downarrow & & \\
 & & Y' & \xlongequal{\quad} & Y' & & \\
 & & \downarrow & & \downarrow & & \\
 0 & \longrightarrow & W & \longrightarrow & Y'' & \longrightarrow & X'' \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \parallel \\
 0 & \longrightarrow & M & \longrightarrow & Z & \longrightarrow & X'' \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \\
 & & 0 & & 0 & & 
 \end{array}$$

we see from the middle column that  $Z$  has finite injective dimension, so the bottom row is a FID hull for  $M$ .  $\square$

**11.17 Notation.** Having now established both existence and uniqueness of minimal MCM approximations and FID hulls, we introduce some notation for them. The minimal MCM approximation of  $M$  is denoted by

$$0 \longrightarrow Y_M \longrightarrow X_M \longrightarrow M \longrightarrow 0,$$

while the minimal FID hull of  $M$  is denoted

$$0 \longrightarrow M \longrightarrow Y^M \longrightarrow X^M \longrightarrow 0.$$

To show off the new notation, here is the final diagram of the proof of Theorem 11.16.

$$(11.17.1) \quad \begin{array}{ccccccc} & & 0 & & 0 & & \\ & & \downarrow & & \downarrow & & \\ & & Y_M & \equiv & Y_M & & \\ & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & X_M & \longrightarrow & \omega^{(n)} & \longrightarrow & X^M \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \parallel \\ 0 & \longrightarrow & M & \longrightarrow & Y^M & \longrightarrow & X^M \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \\ & & 0 & & 0 & & \end{array}$$

Here  $n = \mu_R(X_M^\vee)$  as the middle row is an FID hull for  $X_M$ .

We also record a few curiosities that arose in the proof of Theorem 11.16.

**11.18 Proposition.** *Up to adding or deleting direct summands isomorphic to  $\omega$ , we have*

(i)  $Y_M \cong Y^{\text{syz}_1^R(M)}$ ;

(ii)  $X^M \cong X^{X_M}$ ; and

(iii)  $X_M$  is an extension of a free module by  $X^{\text{syz}_1^R(M)}$ , that is, there is a short exact sequence  $0 \rightarrow F \rightarrow X_M \rightarrow X^{\text{syz}_1^R(M)} \rightarrow 0$  with  $F$  free.

In particular, if  $R$  is Gorenstein then we have as well

(iv)  $X_M \cong X^{\text{syz}_1^R(M)}$ ;

(v)  $X_M \cong \text{syz}_1^R(X^M)$ ; and

(vi)  $Y_M \cong \text{syz}_1^R(Y^M)$ .

We see already that the case of a Gorenstein local ring is special. In this case, finite injective dimension coincides with finite projective dimension, making the theory more tractable. We will see more advantages of the Gorenstein condition in §4; see also Exercises 11.44 and 11.45.

We record here for later reference the case of codepth 1.

**11.19 Proposition.** *Let  $R$  be a CM local ring with canonical module and let  $M$  be an  $R$ -module of codepth 1. Let  $\xi_1, \dots, \xi_t$  be a minimal set of generators for the (nonzero) module  $\text{Ext}_R^1(M, \omega)$ , and let  $E$  be the extension of  $M$  by  $\omega^{(t)}$  corresponding to the element  $\xi = (\xi_1, \dots, \xi_t) \in \text{Ext}_R^1(M, \omega^{(t)}) \cong \text{Ext}_R^1(M, \omega)^{(t)}$ . Then  $E$  is a MCM module and*

$$\xi: 0 \rightarrow \omega^{(t)} \rightarrow E \rightarrow M \rightarrow 0$$

*is the minimal MCM approximation of  $M$ . In particular, this construction coincides with that of Proposition 11.15 if  $M$  is CM, i.e. if  $\text{Hom}_R(M, \omega) = 0$ .*

To close out this section, we have a few more words to say about uniqueness. Since every MCM module is its own MCM approximation, the function  $M \rightsquigarrow X_M$  is in general neither injective nor surjective. However, we

may restrict to CM modules of a fixed codepth and ask whether every MCM module  $X$  is a MCM approximation of a CM module of codepth  $r$ . For  $r = 1$  and  $r = 2$ , these questions have essentially been answered by Yoshino-Isogawa [YI00] and Kato [Kat07]. Here is the criterion for  $r = 1$ .

**11.20 Proposition.** *Let  $R$  be a CM local ring with a canonical module, and assume that  $R$  is generically Gorenstein. Let  $X$  be a MCM  $R$ -module. Then  $X$  is a MCM approximation of some CM module  $M$  of codepth 1 if and only if  $X$  has constant rank.*

*Proof.* First assume that  $X$  has constant rank  $s$ . Then there is a short exact sequence

$$0 \longrightarrow R^{(s)} \longrightarrow X \longrightarrow N \longrightarrow 0$$

in which  $N$  is a torsion module. In particular,  $N$  has dimension at most  $\dim R - 1$ . However, the Depth Lemma ensures that  $N$  has depth at least  $\dim R - 1$ , so  $N$  is CM of codepth 1. As  $R$  is generically Gorenstein, the canonical module  $\omega$  embeds into  $R$  as an ideal of pure height one (Prop. 11.6). We therefore have embeddings  $\omega^{(s)} \hookrightarrow R^{(s)}$  and  $R^{(s)} \hookrightarrow X$  fitting into a commutative diagram

$$\begin{array}{ccccccc} 0 & \longrightarrow & \omega^{(s)} & \longrightarrow & X & \longrightarrow & M \longrightarrow 0 \\ & & \downarrow & & \parallel & & \downarrow \\ 0 & \longrightarrow & R^{(s)} & \longrightarrow & X & \longrightarrow & N \longrightarrow 0. \end{array}$$

The Snake Lemma delivers an isomorphism from the kernel of  $M \rightarrow N$  onto  $(R/\omega)^{(s)}$ , and hence an exact sequence

$$0 \longrightarrow (R/\omega)^{(s)} \longrightarrow M \longrightarrow N \longrightarrow 0.$$

Therefore  $M$  is also CM of codepth 1, and the top row of the diagram is a MCM approximation of  $M$ .

For the converse, suppose that  $M$  is CM of codepth 1 and that  $X$  is a MCM approximation of  $M$ . Then  $X \cong X_M \oplus \omega^{(t)}$  for some  $t \geq 0$ . In the minimal MCM approximation

$$0 \longrightarrow Y_M \longrightarrow X_M \longrightarrow M \longrightarrow 0,$$

we see that  $M$  is torsion, whence of rank zero, and  $Y_M$  is isomorphic to a direct sum of copies of  $\omega$ . As  $R$  is generically Gorenstein,  $Y_M$  has constant rank, and so  $X_M$  and  $X$  do as well.  $\square$

It's clear that a local ring  $R$  is a domain if and only if every finitely generated  $R$ -module has constant rank. If in addition  $R$  is CM, then it follows that  $R$  is a domain if and only if every MCM module has constant rank. (Take a high syzygy of an arbitrary finitely generated module  $M$  and compute the rank of  $M$  as an alternating sum.) These observations prove the following corollary.

**11.21 Corollary.** *Let  $R$  be a CM local ring with a canonical module and assume that  $R$  is generically Gorenstein. The following statements are equivalent.*

- (i) *For every MCM  $R$ -module  $X$ , there exists a CM module  $M$  of codepth 1 such that  $X$  is MCM approximation of  $M$ .*
- (ii)  *$R$  is a domain.*

The question of the injectivity of the function  $M \rightsquigarrow X_M$  for modules  $M$  of a fixed codepth is, as far as we can tell, still open. The corresponding ques-

tion for FID hulls, however, has a positive answer when  $R$  is Gorenstein, due to Kato [Kat99].

### §3 Numerical invariants

Since the minimal MCM approximation and minimal FID hull of a module  $M$  are uniquely determined up to isomorphism by  $M$ , any numerical information we derive from  $X_M$ ,  $Y_M$ ,  $X^M$ , and  $Y^M$  are invariants of  $M$ . For example, if  $R$  is Henselian we might consider the number of indecomposable direct summands appearing in a direct sum decomposition of  $X_M$  or  $Y^M$  as a kind of measure of the complexity of  $M$ , or if  $R$  is generically Gorenstein we might consider  $\text{rank} Y^M$ . All these possibilities were pointed out by Buchweitz [Buc86], but seem not to have gotten much attention. In this section we introduce two other numerical invariants of  $M$ , namely  $\delta(M)$ , first defined by Auslander; and  $\gamma(M)$ , defined by Herzog and Martsinkovsky.

Throughout,  $(R, \mathfrak{m})$  is still a CM local ring with canonical module  $\omega$ . For an arbitrary finitely generated  $R$ -module  $Z$ , we define the *free rank* of  $Z$ , denoted  $\text{f-rank} Z$ , to be the rank of a maximal free direct summand of  $Z$ . In other words,  $Z \cong \underline{Z} \oplus R^{(\text{f-rank} Z)}$  with  $\underline{Z}$  *stable*, i.e. having no non-trivial free direct summands. Dually, the *canonical rank* of  $Z$ ,  $\omega\text{-rank} Z$ , is the largest integer  $n$  such that  $\omega^{(n)}$  is a direct summand of  $Z$ .

**11.22 Definition.** Let  $M$  be a finitely generated  $R$ -module with minimal MCM approximation  $0 \rightarrow Y_M \rightarrow X_M \rightarrow M \rightarrow 0$  and minimal FID hull

$0 \longrightarrow M \longrightarrow Y^M \longrightarrow X^M \longrightarrow 0$ . Then we define

$$\delta(M) = \text{f-rank } X_M; \text{ and}$$

$$\gamma(M) = \omega\text{-rank } X_M.$$

For the rest of the section, we fix once and for all the minimal MCM approximation

$$0 \longrightarrow Y_M \xrightarrow{i} X_M \xrightarrow{p} M \longrightarrow 0$$

and minimal FID hull

$$0 \longrightarrow M \xrightarrow{j} Y^M \xrightarrow{q} X^M \longrightarrow 0$$

of a chosen  $R$ -module  $M$ . Note first that since we chose our approximation and hull to be (Ext-)minimal, we have

$$\text{Ext}_R^d(k, X_M) \cong \text{Ext}_R^d(k, M) \cong \text{Ext}_R^d(k, Y^M),$$

where  $d = \dim R$ . This, together with the fact (see Exercise 11.48) that  $\text{Ext}_R^d(k, Z) \neq 0$  for every non-zero finitely generated  $R$ -module  $Z$ , immediately gives the following crude bounds.

**11.23 Proposition.** *Set  $s = \dim_k \text{Ext}_R^d(k, M)$ . Then*

- (i)  $\delta(M) \cdot \dim_k \text{Ext}_R^d(k, R) \leq s$ , with equality if and only if  $X_M$  is free. In particular, if  $\dim_k \text{Ext}_R^d(k, M) < \dim_k \text{Ext}_R^d(k, R)$ , then  $\delta(M) = 0$ .
- (ii)  $\gamma(M) \leq s$ , with equality if and only if  $M$  has finite injective dimension.

Note that the question of which modules  $M$  satisfy “ $X_M$  is free” is quite subtle. One situation in which it holds is when  $R$  is Gorenstein and  $M$  has

finite projective dimension; see Exercise 11.44. However, it may hold in other cases as well, for example  $M = R/\omega$ , where  $\omega$  is embedded as an ideal of height one as in Prop. 11.6.

To obtain sharper bounds, as well as a better understanding of what exactly each invariant measures, we consider them separately. Of the two,  $\delta(M)$  has received more attention, so we begin there.

**11.24 Lemma.** *Let  $M$  be a finitely generated  $R$ -module. Write  $X_M = \underline{X} \oplus F$ , where  $F$  is a free module of rank  $\delta(M)$  and  $\underline{X}$  is stable. Then*

$$\delta(M) = \mu_R(M/p(\underline{X})).$$

*Proof.* The commutative diagram of short exact sequences

$$\begin{array}{ccccccc}
 & & 0 & & 0 & & 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 0 & \longrightarrow & \ker(p|_{\underline{X}}) & \longrightarrow & Y_M & \longrightarrow & \ker \bar{p} \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 0 & \longrightarrow & \underline{X} & \longrightarrow & X_M & \longrightarrow & F \longrightarrow 0 \\
 & & \downarrow & & \downarrow p & & \downarrow \bar{p} \\
 0 & \longrightarrow & p(\underline{X}) & \longrightarrow & M & \longrightarrow & M/p(\underline{X}) \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 & & 0 & & 0 & & 0
 \end{array}$$

shows that  $\delta(M) = \text{rank } F \geq \mu_R(M/p(\underline{X}))$ . If  $\text{rank } F > \mu_R(M/p(\underline{X}))$ , then  $\ker \bar{p}$  has a non-zero free direct summand. Since  $Y_M$  maps onto  $\ker \bar{p}$ ,  $Y_M$  also has a free summand, which we easily see is a common direct summand of  $Y_M$  and  $X_M$ . As our approximation was chosen minimal, we must have equality.  $\square$

The lemma allows us to characterize  $\delta(M)$  without referring to the MCM approximation of  $M$ .

**11.25 Proposition.** *Let  $M$  be a finitely generated  $R$ -module. The delta-invariant  $\delta(M)$  is the minimum free rank of all MCM modules  $Z$  admitting a surjective homomorphism onto  $M$ .*

*Proof.* Denote the minimum by  $\delta' = \delta'(M)$ , and set  $\delta = \delta(M)$ . Then evidently  $\delta' \leq \delta$ . For the other inequality, let  $\varphi: Z \rightarrow M$  be a surjection with  $Z$  MCM and  $\text{f-rank } Z = \delta'$ . Write  $Z = \underline{Z} \oplus R^{(\delta')}$  and  $X_M = \underline{X} \oplus R^{(\delta)}$ . The lifting property applied to  $\varphi|_{\underline{Z}}$  gives a homomorphism  $\alpha: \underline{Z} \rightarrow \underline{X} \oplus R^{(\delta)}$  fitting into a commutative diagram

$$\begin{array}{ccccccc}
 0 & \longrightarrow & \ker \varphi|_{\underline{Z}} & \longrightarrow & \underline{Z} & \xrightarrow{\varphi|_{\underline{Z}}} & M \\
 & & \downarrow & & \downarrow \alpha & & \parallel \\
 0 & \longrightarrow & Y_M & \longrightarrow & \underline{X} \oplus R^{(\delta)} & \xrightarrow{p} & M \longrightarrow 0
 \end{array}$$

As  $\underline{Z}$  has no free direct summands, the image of the composition  $\underline{Z} \rightarrow \underline{X} \oplus R^{(\delta)} \rightarrow R^{(\delta)}$  is contained in  $\mathfrak{m}R^{(\delta)}$ . Thus  $\alpha(\underline{Z})$  contributes no minimal generators to  $M/p(\underline{X})$ , and therefore  $\delta = \mu_R(M/p(\underline{X})) \leq \mu_R(M/p\alpha(\underline{Z})) \leq \delta'$ . □

In particular, Prop. 11.25 implies that for a MCM module  $X$ , we have  $\delta(X) = \text{f-rank } X$ , and for  $M$  arbitrary,  $\delta(M) = 0$  if and only if  $M$  is a homomorphic image of a stable MCM module. We also obtain some basic properties of  $\delta$ .

**11.26 Corollary.** *Let  $M$  and  $N$  be finitely generated  $R$ -modules.*

(i)  $\delta(M \oplus N) = \delta(M) + \delta(N)$ .

(ii)  $\delta(N) \leq \delta(M)$  if there is a surjection  $M \rightarrow N$ .

(iii)  $\delta(M) \leq \mu_R(M)$ .

*Proof.* Since minimality is equivalent to Ext-minimality, the direct sum of minimal MCM approximations of  $M$  and  $N$  is again minimal. Thus  $X_{M \oplus N} \cong X_M \oplus X_N$ . The free rank of  $X_M \oplus X_N$  is the sum of those of  $X_M$  and  $X_N$ , since a direct sum has a free summand if and only if one summand does. The second and third statements are clear from the Proposition.  $\square$

**11.27 Remark.** We point out a historically significant consequence of Cor. 11.26.

Suppose that  $R$  is Gorenstein and  $M$  is an  $R$ -module equipped with a surjection onto a non-zero module  $N$  of finite projective dimension. Since the minimal MCM approximation of  $N$  is simply a free cover (Ex. 11.44), we have  $\delta(N) > 0$ , and hence  $\delta(M) > 0$ . It was at first conjectured that  $\delta(M) > 0$  if and only if  $M$  has a non-zero quotient module of finite projective dimension, but a counterexample was given by S. Ding [Din94]. Ding proves a formula for  $\delta(R/I)$ , where  $R$  is a one-dimensional Gorenstein local ring and  $I$  is an ideal of  $R$  containing a non-zero-divisor:

$$\delta(R/I) = 1 + \lambda(\text{soc}(R/I)) - \mu_R(I^*).$$

He then takes  $R = k[[t^3, t^4]]$ , where  $k$  is a field, and  $I = (t^8 + t^9, t^{10})$ . He shows that  $\delta(R/I) = 1$  and that  $I$  is not contained in any proper principal ideal of  $R$ , so  $R/I$  cannot map onto a non-zero module of finite projective dimension.

We also mention here in passing a remarkable application of the  $\delta$ -invariant, due to A. Martsinkovsky [Mar90, Mar91]. Let  $S = k[[x_1, \dots, x_n]]$

be a power series ring over an algebraically closed field of characteristic zero. Let  $f \in S$  be a polynomial such that the hypersurface ring  $R = S/(f)$  is an isolated singularity. The Jacobian ideal  $j(f)$ , generated by the partial derivatives of  $f$ , and its image  $\overline{j(f)}$  in  $R$ , are thus primary to the respective maximal ideals. Martsinkovsky shows that  $\delta\left(R/\overline{j(f)}\right) = 0$  if and only if  $f \in j(f)$ . In fact, these are equivalent to  $f \in (x_1, \dots, x_n)j(f)$ , which by a foundational result of Saito [Sai71] occurs if and only if  $f$  is *quasi-homogeneous*, i.e. there is an integral weighting of the variables  $x_1, \dots, x_n$  under which  $f$  is homogeneous.

Turning now to  $\gamma(M) = \omega\text{-rank } X_M$ , we have an analogue of Lemma 11.24, the proof of which is similar enough that we skip it.

**11.28 Lemma.** *Let  $M$  be a finitely generated  $R$ -module, and write  $X_M = \overline{X} \oplus \omega^{(\gamma(M))}$ , where  $\overline{X}$  has no direct summand isomorphic to  $\omega$ . Then*

$$\gamma(M) \cdot \mu_R(\omega) = \mu_R\left(M/p(\overline{X})\right).$$

As a consequence, we find an unexpected restriction on the  $R$ -modules of finite injective dimension.

**11.29 Proposition.** *Let  $M$  be a finitely generated  $R$ -module of finite injective dimension. Then  $\gamma(M) \cdot \mu_R(\omega) = \mu_R(M)$ . In particular,  $\mu_R(M)$  is an integer multiple of  $\mu_R(\omega)$ .*

There is obviously no direct analogue of Prop. 11.25 for  $\gamma(M)$ ; as long as  $R$  is not Gorenstein, every  $M$  is a homomorphic image of a MCM module without  $\omega$ -summands, namely, a free module. Still, we do retain additivity, and in certain cases the other assertions of Cor. 11.26.

**11.30 Proposition.** *Let  $M$  and  $N$  be  $R$ -modules. Then  $\gamma(M \oplus N) = \gamma(M) + \gamma(N)$ .*

The next result fails without the assumption of finite injective dimension. For example, consider a non-Gorenstein ring  $R$  and a free module  $F$  mapping onto the canonical module  $\omega$ . We have  $\gamma(F) = 0$  and  $\gamma(\omega) = 1$ .

**11.31 Proposition.** *Let  $N \subseteq M$  be  $R$ -modules, both of finite injective dimension. Then  $\gamma(M/N) \leq \gamma(M) - \gamma(N)$ .*

*Proof.* Since each of  $M$ ,  $N$ , and  $M/N$  has finite injective dimension, Prop. 11.23 allows us to compute  $\gamma(-)$  as  $\dim_k \text{Ext}_R^d(k, -)$ . The long exact sequence of Ext ends with

$$\text{Ext}_R^d(k, N) \longrightarrow \text{Ext}_R^d(k, M) \longrightarrow \text{Ext}_R^d(k, M/N) \longrightarrow 0,$$

and a dimension count gives the inequality.  $\square$

In case  $M$  has codepth 1, the explicit construction of MCM approximations in Prop. 11.19 allows us to compute  $\gamma(M)$  directly. We leave the proof as yet another exercise.

**11.32 Proposition.** *Let  $M$  be an  $R$ -module of codepth 1 (not necessarily Cohen-Macaulay). Then we have  $\gamma(M) = \mu_R(\text{Ext}_R^1(M, \omega))$ .*

For CM modules, the  $\delta$ - and  $\gamma$ -invariants are dual. This follows easily from the construction of MCM approximations in this case.

**11.33 Proposition.** *Let  $M$  be a CM  $R$ -module of codepth  $t$ , and write  $M^\vee = \text{Ext}_R^t(M, \omega)$  as usual. Then  $\delta(M^\vee) = \gamma(\text{syz}_t^R(M))$ .*

In fact, one can show, using the gluing construction of Herzog and Mart-sinkovsky [HM93], that  $\delta(\text{syz}_i(M^\vee)) = \gamma(\text{syz}_{t-i}(M))$  for  $i = 0, \dots, t$ .

When  $R$  is Gorenstein,  $\delta$  and  $\gamma$  coincide, allowing us to combine all the above results, and enabling new ones. Here is an example.

**11.34 Proposition.** *Assume that  $R$  is a Gorenstein ring, and let  $M$  be a finitely generated  $R$ -module. Then*

$$\delta(M) = \mu_R(Y^M) - \mu_R(X^M).$$

*Proof.* Consider the diagram (11.17.1) following the construction of MCM approximations and FID hulls. In the Gorenstein situation, the  $\omega^{(n)}$  in the center becomes a free module  $R^{(n)}$ . Thus  $\delta(M) = \text{f-rank } X_M = n - \mu_R(X^M)$ . The middle column implies  $n \geq \mu_R(Y^M)$ , but in fact we have equality: the image of the vertical arrow  $Y_M \rightarrow R^n$  is contained in  $\mathfrak{m}R^{(n)}$  by the minimality of the left-hand column. Combining these gives the formula of the statement.  $\square$

## §4 The index and applications to finite CM type

Once again, in this section  $(R, \mathfrak{m})$  is a CM local ring with canonical module  $\omega$ . As a warm-up exercise, here is a straightforward result attributed to Auslander.

**11.35 Proposition.** *The following conditions are equivalent.*

- (i)  $R$  is a regular local ring.

(ii)  $\delta(\text{syz}_n^R(k)) > 0$  for all  $n \geq 0$ .

(iii)  $\delta(k) = 1$ , i.e.  $k$  is not a homomorphic image of a stable MCM module.

(iv)  $\gamma(\text{syz}_d^R(k)) > 0$ , where  $d = \dim R$ .

*Proof.* If  $R$  is a regular local ring, then every MCM module is free, so  $\delta(M) > 0$  for every module  $M$  in particular (ii) holds. Statement (ii) implies (iii) trivially. If  $R$  is non-regular, then there is at least one MCM  $R$ -module  $M$  without free summands, and the composition  $M \rightarrow M/\mathfrak{m}M \cong k^{(\mu_R(M))} \rightarrow k$  shows  $\delta(k) = 0$ . Thus the first three statements are equivalent. Finally, the construction of minimal MCM approximations for CM modules in Prop. 11.15 shows that  $\delta(k) = \text{f-rank}(\text{syz}_d^R(k^\vee)^\vee) = \omega\text{-rank}(\text{syz}_d^R(k)) = \gamma(\text{syz}_d^R(k))$ , whence (iii)  $\iff$  (iv).  $\square$

For a moment, let us set  $\delta_n = \delta(R/\mathfrak{m}^n)$  for each  $n \geq 0$ . Then the Proposition says simply that if  $R$  is not regular, then  $\delta_0 = 0$ . The surjection  $R/\mathfrak{m}^{n+1} \rightarrow R/\mathfrak{m}^n$  gives  $\delta_{n+1} \geq \delta_n$ , and every  $\delta_n$  is at most 1 by Cor. 11.26. Thus the sequence  $\{\delta_n\}$  is non-decreasing, with

$$0 = \delta_0 \leq \delta_1 \leq \cdots \leq \delta_n \leq \delta_{n+1} \leq \cdots \leq 1.$$

If ever  $\delta_n = 1$ , the sequence stabilizes there. Let us define the *index of  $R$*  to be the point at which that stabilization occurs, that is,

$$\text{index}(R) = \min \{ n \mid \delta(R/\mathfrak{m}^n) = 1 \}$$

and set  $\text{index}(R) = \infty$  if  $\delta(R/\mathfrak{m}^n) = 0$  for every  $n$ . Equivalently,  $\text{index}(R)$  is the least integer  $n$  such that any MCM  $R$ -module  $X$  mapping onto  $R/\mathfrak{m}^n$

has a free direct summand. In these terms, the Proposition says that  $R$  is regular if and only if  $\text{index}(R) = 1$ .

Next we point out that the index of  $R$  is finite if  $R$  is Gorenstein. Let  $\mathbf{x}$  be a system of parameters in the maximal ideal  $\mathfrak{m}$ . Then  $R/(\mathbf{x})$  has finite projective dimension, so  $\delta(R/(\mathbf{x})) > 0$  since the MCM approximation is just a free cover (Exercise 11.44). The ideal generated by  $\mathbf{x}$  being  $\mathfrak{m}$ -primary, we have  $\mathfrak{m}^n \subseteq (\mathbf{x})$  for some  $n$ , and the surjection  $R/\mathfrak{m}^n \rightarrow R/(\mathbf{x})$  gives  $\delta_n \geq \delta(R/(\mathbf{x})) > 0$ . Thus  $\text{index}(R) \leq n$ . In fact, we see that the index of  $R$  is bounded above by the *generalized Loewy length* of  $R$ ,

$$\ell(R) = \inf \{ n \mid \text{there exists a s.o.p. } \mathbf{x} \text{ with } \mathfrak{m}^n \subseteq (\mathbf{x}) \}.$$

It has been conjectured by Ding that in fact  $\text{index}(R) = \ell(R)$ ; as long as the residue field of  $R$  is infinite [HS97], this is still open, despite partial results by Ding [Din92, Din93, Din94] and Herzog [Her94], who proved it in case  $R$  is homogeneous graded over a field.

In this section we will give Ding's proof that the index of  $R$  is finite if and only if  $R$  is Gorenstein on the punctured spectrum; moreover, in this case the index is bounded by the Loewy length. This will be Theorem 11.39, to which we come after some preliminaries.

**11.36 Lemma.** *Let  $(R, \mathfrak{m})$  be a CM local ring with canonical module  $\omega$  and let  $x \in \mathfrak{m}$  be a non-zerodivisor. Then  $\delta(R/(x)) > 0$  if and only if  $\text{syz}_1^R(\omega/x\omega)$  has a direct summand isomorphic to  $\omega$ .*

*Proof.* The minimal MCM approximation of a module of codepth 1 is computed in Prop. 11.19; in the case of  $R/(x)$  we see that it is obtained by

dualizing a free resolution of  $(R/(x))^\vee = \text{Ext}_R^1(R/(x), \omega) \cong \omega_{R/(x)} \cong \omega/x\omega$ . It therefore takes the form

$$0 \longrightarrow F^\vee \longrightarrow \text{syz}_1^R(\omega/x\omega)^\vee \longrightarrow R/(x) \longrightarrow 0$$

where  $F$  is a free module. Thus  $\delta(R/(x)) = \text{f-rank}(\text{syz}_1^R(\omega/x\omega)^\vee)$  is equal to  $\omega\text{-rank}(\text{syz}_1^R(\omega/x\omega))$ .  $\square$

**11.37 Lemma.** *The following are equivalent for a non-zerodivisor  $x \in \mathfrak{m}$ :*

- (i)  $\text{syz}_1^R(\omega/x\omega)$  has a direct summand isomorphic to  $\omega$ ;
- (ii)  $\text{syz}_1^R(\omega/x\omega) \cong \omega \oplus \text{syz}_1^R(\omega)$ ;
- (iii) the multiplication map  $\omega \xrightarrow{x} \omega$  factors through a free module.

*Proof.* (i)  $\implies$  (ii) Form the pullback of a free cover  $F \longrightarrow \omega/x\omega$  and the surjection  $\omega \longrightarrow \omega/x\omega$  to obtain a diagram as below.

$$\begin{array}{ccccccc}
 & & & 0 & & 0 & \\
 & & & \downarrow & & \downarrow & \\
 & & & \text{syz}_1^R(\omega/x\omega) & \cong & \text{syz}_1^R(\omega/x\omega) & \\
 & & & \downarrow & & \downarrow & \\
 0 & \longrightarrow & \omega & \longrightarrow & P & \longrightarrow & F \longrightarrow 0 \\
 & & \parallel & & \downarrow & & \downarrow & \\
 0 & \longrightarrow & \omega & \longrightarrow & \omega & \longrightarrow & \omega/x\omega \longrightarrow 0 \\
 & & & & \downarrow & & \downarrow & \\
 & & & & 0 & & 0 & 
 \end{array}$$

The middle row splits, giving a short exact sequence

$$0 \longrightarrow \text{syz}_1^R(\omega/x\omega) \longrightarrow F \oplus \omega \longrightarrow \omega \longrightarrow 0$$

in the middle column. As  $\text{Ext}_R^1(\omega, \omega) = 0$ , any  $\omega$ -summand of  $\text{syzy}_1^R(\omega/x\omega)$  must split out as an isomorphism  $\omega \rightarrow \omega$ , leaving  $\text{syzy}_1^R(\omega)$  behind.

(ii)  $\implies$  (iii) Letting  $F \rightarrow \omega$  now be a free cover of  $\omega$ , another pullback gives the diagram

$$\begin{array}{ccccccc}
 & & 0 & & 0 & & \\
 & & \downarrow & & \downarrow & & \\
 & & \text{syzy}_1^R(\omega) & \xlongequal{\quad} & \text{syzy}_1^R(\omega) & & \\
 & & \downarrow & & \downarrow & & \\
 0 & \longrightarrow & \text{syzy}_1^R(\omega/x\omega) & \longrightarrow & F & \longrightarrow & \omega/x\omega \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \parallel \\
 0 & \longrightarrow & \omega & \xrightarrow{x} & \omega & \longrightarrow & \omega/x\omega \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \\
 & & 0 & & 0 & & 
 \end{array}$$

Applying Miyata's theorem (Theorem 7.1), the left-hand column must split, so that  $\omega \xrightarrow{x} \omega$  factors through  $F$ .

(iii)  $\implies$  (i) If we have a factorization of the multiplication homomorphism  $\omega \xrightarrow{x} \omega$  through a free module, say  $\omega \rightarrow G \rightarrow \omega$ , we may pull back in two stages:

$$\begin{array}{ccccccc}
 0 & \longrightarrow & \text{syzy}_1^R(\omega) & \longrightarrow & Q & \longrightarrow & \omega \longrightarrow 0 \\
 & & \parallel & & \downarrow & & \downarrow \\
 0 & \longrightarrow & \text{syzy}_1^R(\omega) & \longrightarrow & P & \longrightarrow & G \longrightarrow 0 \\
 & & \parallel & & \downarrow & & \downarrow \\
 0 & \longrightarrow & \text{syzy}_1^R(\omega) & \longrightarrow & F & \longrightarrow & \omega \longrightarrow 0
 \end{array}$$

The result is the same as if we had pulled back by  $\omega \xrightarrow{x} \omega$  directly, by the functoriality of Ext. Doing so in two stages, however, reveals that the

middle row splits as  $G$  is free, and so the top row splits as well. This gives  $Q \cong \omega \oplus \text{syz}_1^R(\omega)$  and the middle column thus presents  $Q$  as the first syzygy of  $\text{cok}(\omega \xrightarrow{x} \omega) \cong \omega/x\omega$ , giving even property (ii) and in particular (i).  $\square$

Putting the lemmas together, we see that  $\delta(R/(x)) = 0$  for a nonzerodivisor  $x \in \mathfrak{m}$  if and only if  $x$  is in the ideal of  $\text{End}_R(\omega) \cong R$  consisting of those elements for which the corresponding multiplication factors through a free module. Let us identify this ideal explicitly.

**11.38 Lemma.** *Let  $R$  be a CM local ring with canonical module  $\omega$ . The following three ideals of  $R$  coincide.*

(i)  $\{x \in R \mid \omega \xrightarrow{x} \omega \text{ factors through a free module}\};$

(ii) *the trace  $\tau_\omega(R)$  of  $\omega$  in  $R$ , which is generated by all homomorphic images of  $\omega$  in  $R$ ;*

(iii) *the image of the natural map*

$$\alpha: \text{Hom}_R(\omega, R) \otimes_R \omega \longrightarrow \text{End}_R(\omega) = R$$

*defined by  $\alpha(f \otimes a)(b) = f(b) \cdot a$ . (Note that this is not the evaluation map  $\text{ev}(f \otimes a) = f(a)$ .)*

*Proof.* We prove (i)  $\supseteq$  (ii)  $\supseteq$  (iii)  $\supseteq$  (i).

Let  $x \in \tau_\omega(R)$ , so that there is a linear functional  $f: \omega \rightarrow R$  and an element  $a \in \omega$  with  $f(a) = x$ . Defining  $g: R \rightarrow \omega$  by  $g(1) = a$ , we have a factorization  $x = g \circ f: \omega \rightarrow \omega$ .

Now if  $x \in \text{im } \alpha$ , then there exist homomorphisms  $f_i: \omega \rightarrow R$  and elements  $a_i \in \omega$  such that

$$\alpha \left( \sum_i f_i \otimes a_i \right) (b) = xb$$

for every  $b \in \omega$ . Define homomorphisms  $g_i: \omega \rightarrow R$  by  $g_i(b) = \alpha(f_i \otimes b)$  for all  $b \in \omega$ . Then  $\sum_i g_i(a_i) = x$ , so that  $x$  is contained in the sum of the images of the  $g_i$ , hence in the trace ideal.

Finally, suppose we have a commutative diagram

$$\begin{array}{ccc} \omega & \xrightarrow{x} & \omega \\ & \searrow \Sigma f_i & \nearrow \Sigma g_i \\ & F & \end{array}$$

with  $F$  a free module and  $\Sigma f_i, \Sigma g_i$  the decompositions along an isomorphism  $F \cong R^{(n)}$ . Then for  $a \in \omega$ , we have

$$\begin{aligned} \alpha \left( \sum f_i \otimes g_i(1) \right) (a) &= \sum f_i(a) \cdot g_i(1) \\ &= \sum g_i(f_i(a)) \\ &= xa \end{aligned}$$

so that  $x \in \text{im } \alpha$ . □

From either of the first two descriptions above, we see that  $1 \in \tau_\omega(R)$  if and only if  $R$  is Gorenstein. It follows that  $\tau_\omega(R)$  defines the *Gorenstein locus* of  $R$ , that is, a localization  $R_{\mathfrak{p}}$  is Gorenstein if and only if  $\tau_\omega(R) \not\subseteq \mathfrak{p}$ . In particular,  $R$  is Gorenstein on the punctured spectrum if and only if  $\tau_\omega(R)$  is  $\mathfrak{m}$ -primary.

**11.39 Theorem (Ding).** *The index of a CM local ring  $(R, \mathfrak{m})$  with canonical module  $\omega$  is finite if and only if  $R$  is Gorenstein on the punctured spectrum.*

*Proof.* Assume first that  $R$  is Gorenstein on the punctured spectrum, so that  $\tau_\omega(R)$  is  $\mathfrak{m}$ -primary. Then there exists a regular sequence  $x_1, \dots, x_d$  in  $\tau_\omega(R)$ , where  $d = \dim R$ . We claim by induction on  $d$  that  $\delta(R/(x_1, \dots, x_d)) \neq 0$ . The case  $d = 1$  is immediate from Lemmas 11.36 and 11.37.

Suppose  $d > 1$  and  $X$  is a MCM  $R$ -module with a surjection  $X \rightarrow R/(x_1, \dots, x_d)$ . Tensor with  $\bar{R} = R/(x_1)$  to get a surjection  $X/x_1X \rightarrow \bar{R}/(\bar{x}_2, \dots, \bar{x}_d)$ , where overlines indicate passage to  $\bar{R}$ . Since  $\bar{x}_2, \dots, \bar{x}_d$  are in  $\tau_\omega(\bar{R})$ , the inductive hypothesis says that  $X/x_1X$  has an  $R/(x_1)$ -free direct summand. But then there is a surjection  $X \rightarrow X/x_1X \rightarrow \bar{R}$ , so that  $\text{f-rank } X \geq \delta(\bar{R}) > 0$ , and  $X$  has a non-trivial  $R$ -free direct summand, showing  $\delta(R/(x_1, \dots, x_d)) > 0$ .

Now let us assume that  $\tau_\omega(R)$  is not  $\mathfrak{m}$ -primary. For any power  $\mathfrak{m}^n$  of the maximal ideal, we may find a non-zero-divisor  $z_{(n)} \in \mathfrak{m}^n \setminus \tau_\omega(R)$ . By Lemmas 11.36 and 11.37,  $\delta(R/(z_{(n)})) = 0$  for every  $n$ , and the surjection  $R/(z_{(n)}) \rightarrow R/\mathfrak{m}^n$  gives  $\delta(R/\mathfrak{m}^n) = 0$  for all  $n$ , so that  $\text{index}(R) = \infty$ .  $\square$

As an application of Ding's theorem, we prove that CM local rings of finite CM type are Gorenstein on the punctured spectrum. Of course this follows trivially from Theorem 7.12, since isolated singularities are Gorenstein on the punctured spectrum. This proof is completely independent, however, and may have other applications. It relies upon Guralnick's results in Section §3 of Chapter 7.

**11.40 Theorem.** *Let  $(R, \mathfrak{m})$  be a CM local ring of finite CM type. Then  $R$  has finite index. If in particular  $R$  has a canonical module, then  $R$  is Gorenstein on the punctured spectrum.*

*Proof.* Let  $\{M_1, \dots, M_r\}$  be a complete set of representatives for the isomorphism classes of non-free indecomposable MCM  $R$ -modules. By Corollary 1.14, since  $R$  is not a direct summand of any  $M_i$ , there exist integers  $n_i$ ,  $i = 1, \dots, r$ , such that for  $s \geq n_i$ ,  $R/\mathfrak{m}^s$  is not a direct summand of  $M_i/\mathfrak{m}^s M_i$ . Then for  $s \geq n_i$ , there exists no surjection  $M_i/\mathfrak{m}^s M_i \rightarrow R/\mathfrak{m}^s$  by Lemma 1.12. Set  $N = \max\{n_i\}$ . Let  $X$  be any stable MCM  $R$ -module, and decompose  $X \cong M_1^{(a_1)} \oplus \dots \oplus M_r^{(a_r)}$ . If there were a surjection  $X \rightarrow R/\mathfrak{m}^N$ , then (since  $R$  is local) one of the summands  $M_i$  would map onto  $R/\mathfrak{m}^N$ , contradicting the choice of  $N$ . As  $X$  was arbitrary, this shows that  $\text{index}(R) < \infty$ .  $\square$

**11.41 Remark.** The foundation of Ding's theorem is in identifying the non-zerodivisors  $x$  such that  $\delta(R/(x)) > 0$ . One might also ask about  $\delta(\omega/x\omega)$ , as well as the corresponding values of the  $\gamma$ -invariant. It's easy to see that the minimal MCM approximation of  $\omega/x\omega$  is the short exact sequence  $0 \rightarrow \omega \xrightarrow{x} \omega \rightarrow \omega/x\omega \rightarrow 0$ , which gives  $\delta(\omega/x\omega) = 0$  and  $\gamma(\omega/x\omega) = 1$ . However,  $\gamma(R/(x))$  is much more mysterious. We have  $X_{R/(x)} \cong \text{syz}_1^R(\omega/x\omega)^\vee$ , so  $\gamma(R/(x)) > 0$  if and only if  $\text{syz}_1^R(\omega/x\omega)$  has a non-zero free direct summand. We know of no effective criterion for this.

**11.42 Remark.** As a final note, we observe that Auslander's criterion for regularity, Proposition 11.35, can be interpreted via the construction of MCM approximations for CM modules in Proposition 11.15. Assume that  $R$  is Gorenstein. Then condition (iv) can be written  $\delta(\text{syz}_d^R(k)) > 0$ , and since  $\text{syz}_d^R(k)$  is MCM, this says simply that  $R$  is regular if and only if  $\text{syz}_d^R(k)$  has a non-trivial free direct summand. This is a special case of a result of Herzog [Her94], which generalizes a case of Levin's solution of a conjec-

ture of Kaplansky: if there exists a finitely generated  $R$ -module  $M$  such that  $\mathfrak{m}M \neq 0$  and  $\mathfrak{m}M$  has finite projective dimension, then  $R$  is regular; in particular, if  $\text{syz}_d^R(R/\mathfrak{m}^n)$  is free for some  $n$  then  $R$  is regular. Yoshino has conjectured [Yos98] that for any positive integers  $t$  and  $n$ ,  $\delta(\text{syz}_t^R(R/\mathfrak{m}^n)) > 0$  if and only if  $R$  is regular local, and has proven the conjecture when  $R$  is Gorenstein and the associated graded ring  $\text{gr}_{\mathfrak{m}}(R)$  has depth at least  $d - 1$ .

## §5 Exercises

**11.43 Exercise.** Prove that the canonical module of a CM local ring is unique up to isomorphism, using the Artinian case and Corollary 1.14.

**11.44 Exercise.** Assume that  $R$  is Gorenstein and  $M$  is an  $R$ -module of finite projective dimension. Then the minimal MCM approximation of  $M$  is just a minimal free cover.

**11.45 Exercise.** Let  $R$  be a CM local ring with canonical module  $\omega$ , and let  $M$  be a finitely generated  $R$ -module of finite injective dimension. Show that  $M$  has a finite resolution by copies of  $\omega$

$$0 \longrightarrow \omega^{n_t} \longrightarrow \cdots \longrightarrow \omega^{n_1} \longrightarrow \omega^{n_0} \longrightarrow M \longrightarrow 0.$$

**11.46 Exercise.** Let  $x \in \mathfrak{m}$  be a non-zero-divisor. Prove that  $X^{R/(x)} \cong \text{syz}_2^R(\omega/x\omega)^\vee$ .

**11.47 Exercise.** Let  $R$  be CM local and  $M$  a finitely generated  $R$ -module. Define the *stable MCM trace* of  $M$  to be the submodule  $\tau(M)$  generated by all homomorphic images  $f(X)$ , where  $X$  is a stable MCM module and  $f \in \text{Hom}_R(X, M)$ . Show that  $\delta(M) = \mu_R(M/\tau(M))$ .

**11.48 Exercise.** Let  $(R, \mathfrak{m})$  be a local ring. Denote by  $\mu^i(\mathfrak{p}, M)$  the number of copies of the injective hull of  $R/\mathfrak{p}$  appearing at the  $i^{\text{th}}$  step of a minimal injective resolution of  $M$ . This integer is called the  $i^{\text{th}}$  Bass number of  $M$  at  $\mathfrak{p}$ . It is equal to the vector-space dimension of  $\text{Ext}_R^i(R/\mathfrak{p}, M)_{\mathfrak{p}}$  over the field  $(R/\mathfrak{p})_{\mathfrak{p}}$ .

- (i) If  $\mu^i(\mathfrak{p}, M) > 0$  and  $\text{height } \mathfrak{q}/\mathfrak{p} = 1$ , prove that  $\mu^{i+1}(\mathfrak{q}, M) > 0$ .
- (ii) If  $M$  has infinite injective dimension, prove that  $\mu^i(\mathfrak{m}, M) > 0$  for all  $i \geq \dim M$ . (Hint: go by induction on  $\dim M$ , the base case being easy. For the inductive step, distinguish two cases: (a)  $\text{injdim}_{R_{\mathfrak{p}}}(M_{\mathfrak{p}}) = \infty$  for some prime  $\mathfrak{p} \neq \mathfrak{m}$ , or (b)  $\text{injdim}_{R_{\mathfrak{p}}}(M_{\mathfrak{p}}) < \infty$  for every  $\mathfrak{p} \neq \mathfrak{m}$ . In the first case, use the previous part of this exercise; in the second, conclude that  $\text{injdim}_R(M) < \infty$ .)

In particular,  $\text{Ext}_R^{\dim R}(k, Z) \neq 0$  for every finitely generated  $R$ -module  $Z$ .

**11.49 Exercise.** This exercise gives a proof of the last remaining implication in Proposition 11.14, following [SS02]. Let  $(R, \mathfrak{m}, k)$  be a CM complete local ring of dimension  $d$  with canonical module  $\omega$ .

- (i) Let  $M$  be a MCM  $R$ -module with minimal injective resolution  $I^{\bullet}$ . Prove that  $\text{Ext}_R^d(k, M) = \text{socle}(I^d)$  is an essential submodule of the local cohomology  $H_{\mathfrak{m}}^d(M) = H^d(\Gamma(I^{\bullet}))$ .
- (ii) Let  $M$  and  $N$  be finitely generated  $R$ -modules with  $M$  MCM and  $N$  having FID. Let  $f: N \rightarrow M$  be a homomorphism. Prove that the  $\omega$ -rank of  $f$  (that is, the number of direct summands isomorphic to  $\omega$  common to  $N$  and  $M$  via  $f$ ) is equal to the  $k$ -dimension of the

image of the homomorphism  $\text{Ext}_R^d(k, f)$ . (Hint: take a MCM approximation of  $N$ , and split the middle term  $X_N \cong \omega^{(n)}$  according to the image of  $\text{Ext}_R^d(k, f)$ . Apply the first part above to the composition  $\text{Ext}_R^d(k, \omega^{(n_1)}) \rightarrow H_{\mathfrak{m}}^d(M)$ , then use local duality.)

**11.50 Exercise.** Let  $R$  be a Gorenstein local ring (or, more generally, a CM local ring with canonical module  $\omega$  and satisfying  $\tau_{\omega}(R) \cong \mathfrak{m}$ ) with infinite residue field. Assume that  $R$  is not regular. Then

$$e(R) \geq \mu_R(\mathfrak{m}) - \dim R - 1 + \text{index}(R).$$

In particular, if  $R$  has *minimal multiplicity*  $e(R) = \mu_R(\mathfrak{m}) - \dim R + 1$ , then  $\text{index}(R) = 2$ . (Compare with Corollary 6.34.)

# 12

## *Auslander-Reiten theory*

In this chapter we give an introduction to Auslander–Reiten sequences, also known as almost split sequences, and the Auslander–Reiten quiver. AR sequences are certain short exact sequences which were first introduced in the representation theory of Artin algebras, where they have played a central role. They have since been used fruitfully throughout representation theory. The information contained within the AR sequences is conveniently arranged in the AR quiver, which in some sense gives a picture of the whole category of MCM modules. We illustrate with several examples in §3.

### §1 AR sequences

For this section,  $(R, \mathfrak{m}, k)$  will be a Henselian CM local ring with a canonical module  $\omega$ .

We begin with the definition.

**12.1 Definition.** Let  $M$  and  $N$  be indecomposable MCM  $R$ -modules, and let

$$(12.1.1) \quad 0 \longrightarrow N \xrightarrow{i} E \xrightarrow{p} M \longrightarrow 0$$

be a short exact sequence of  $R$ -modules.

- (i) We say that (12.1.1) is an *AR sequence ending in  $M$*  if it is non-split, but for every MCM module  $X$  and every homomorphism  $f: X \rightarrow M$  which is not a split surjection,  $f$  factors through  $p$ .

- (ii) We say that (12.1.1) is an *AR sequence starting from  $N$*  if it is non-split, but for every MCM module  $Y$  and every homomorphism  $g: N \rightarrow Y$  which is not a split injection,  $g$  lifts through  $i$ .

We will be concerned almost exclusively with AR sequences ending in a module, and in fact will often call (12.1.1) an AR sequence *for  $M$* . In fact, the two halves of the definition are equivalent; see Exercise 12.41. We will therefore even allow ourselves to call (12.1.1) *an AR sequence* without further qualification if it satisfies either condition.

Observe that if (12.1.1) is an AR sequence, then in particular it is non-split, so that  $M$  is not free and  $N$  is not isomorphic to the canonical module  $\omega$ .

As with MCM approximations, we take care of the uniqueness of AR sequences first, then consider existence.

**12.2 Proposition.** *Suppose that  $0 \rightarrow N \xrightarrow{i} E \xrightarrow{p} M \rightarrow 0$  and  $0 \rightarrow N' \xrightarrow{i'} E' \xrightarrow{p'} M \rightarrow 0$  are two AR sequences for  $M$ . Then there is a commutative diagram*

$$\begin{array}{ccccccc}
 0 & \longrightarrow & N & \xrightarrow{i} & E & \xrightarrow{p} & M \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \parallel \\
 0 & \longrightarrow & N' & \xrightarrow{i'} & E' & \xrightarrow{p'} & M \longrightarrow 0
 \end{array}$$

*in which the first and second vertical maps are isomorphisms.*

*Proof.* Since both sequences are AR sequences for  $M$ , neither  $p$  nor  $p'$  is a split surjection. Therefore each factors through the other, giving a commu-

tative diagram

$$\begin{array}{ccccccccc}
 0 & \longrightarrow & N & \xrightarrow{i} & E & \xrightarrow{p} & M & \longrightarrow & 0 \\
 & & \downarrow \psi & & \downarrow \varphi & & \parallel & & \\
 0 & \longrightarrow & N' & \xrightarrow{i'} & E' & \xrightarrow{p'} & M & \longrightarrow & 0 \\
 & & \downarrow \psi' & & \downarrow \varphi' & & \parallel & & \\
 0 & \longrightarrow & N & \xrightarrow{i} & E & \xrightarrow{p} & M & \longrightarrow & 0
 \end{array}$$

with exact rows.

Consider  $\psi'\psi \in \text{End}_R(N)$ . If  $\psi'\psi$  is a unit of this nc-local ring, then  $\psi'\psi$  is an isomorphism, so  $\psi$  is a split injection. As  $N$  and  $N'$  are both indecomposable,  $\psi$  is an isomorphism, and  $\varphi$  is as well by the Snake Lemma.

If  $\psi'\psi$  is not a unit of  $\text{End}_R(N)$ , then  $\sigma := 1_N - \psi'\psi$  is. Define  $\tau : E \rightarrow N$  by  $\tau(e) = e - \varphi'\varphi(e)$ . This has image in  $N$  since  $p\varphi'\varphi(e) = p(e)$  for all  $e$  by the commutativity of the diagram. Now  $\tau(i(n)) = \sigma(n)$  for every  $n \in N$ . Since  $\sigma$  is a unit of  $\text{End}_R(N)$ , this implies that  $i$  is a split surjection, contradicting the assumption that the top row is an AR sequence. □

For existence of AR sequences, we first observe that we will need to impose an additional restriction on  $M$  or  $R$ .

**12.3 Proposition.** *Assume that there exists an AR sequence for  $M$ . Then  $M$  is locally free on the punctured spectrum of  $R$ . In particular, if every indecomposable MCM  $R$ -module has an AR sequence, then  $R$  has at most an isolated singularity.*

*Proof.* Let  $\alpha : 0 \rightarrow N \rightarrow E \rightarrow M \rightarrow 0$  be an AR sequence for  $M$ . Since  $\alpha$  is non-split,  $M$  is not free. Let  $L = \text{syz}_1^R(M)$ , so that there is a short exact sequence

$$0 \longrightarrow L \longrightarrow F \longrightarrow M \longrightarrow 0$$

with  $F$  a finitely generated free module. Suppose that  $M_{\mathfrak{p}}$  is not free for some prime ideal  $\mathfrak{p} \neq \mathfrak{m}$ . Then

$$0 \longrightarrow L_{\mathfrak{p}} \longrightarrow F_{\mathfrak{p}} \longrightarrow M_{\mathfrak{p}} \longrightarrow 0$$

is still non-split, so in particular  $\text{Ext}_{R_{\mathfrak{p}}}^1(M_{\mathfrak{p}}, L_{\mathfrak{p}}) = \text{Ext}_R^1(M, L)_{\mathfrak{p}}$  is non-zero. Choose an indecomposable direct summand  $K$  of  $L$  such that  $\text{Ext}_R^1(M, K)_{\mathfrak{p}}$  is non-zero, and let  $\beta \in \text{Ext}_R^1(M, K)$  be such that  $\frac{\beta}{1} \neq 0$  in  $\text{Ext}_R^1(M, K)_{\mathfrak{p}}$ . Then the annihilator of  $\beta$  is contained in  $\mathfrak{p}$ . Let  $r \in \mathfrak{m} \setminus \mathfrak{p}$ . Then for every  $n \geq 0$ ,  $r^n \notin \mathfrak{p}$ , so that  $r^n \beta \neq 0$ . In particular  $r^n \beta$  is represented by a non-split short exact sequence for all  $n \geq 0$ . Choosing a representative  $0 \rightarrow K \rightarrow G \rightarrow M \rightarrow 0$  for  $\beta$ , and representatives  $0 \rightarrow K \rightarrow G_n \rightarrow M \rightarrow 0$  for each  $r^n \beta$  as well, we obtain a commutative diagram

$$\begin{array}{ccccccc}
 \beta: & 0 & \longrightarrow & K & \longrightarrow & G & \longrightarrow & M & \longrightarrow & 0 \\
 & & & \downarrow r^n & & \downarrow & & \parallel & & \\
 r^n \beta: & 0 & \longrightarrow & K & \longrightarrow & G_n & \longrightarrow & M & \longrightarrow & 0 \\
 & & & \downarrow f_n & & \downarrow & & \parallel & & \\
 \alpha: & 0 & \longrightarrow & N & \longrightarrow & E & \longrightarrow & M & \longrightarrow & 0
 \end{array}$$

with exact rows. The top half of this diagram is the pushout representing  $r^n \beta$  as a multiple of  $\beta$ , while the vertical arrows in the bottom half are provided by the lifting property of AR sequences. Let  $f_{n*} : \text{Ext}_R^1(M, K) \rightarrow \text{Ext}_R^1(M, N)$  denote the homomorphism induced by  $f_n$ . Then  $\alpha = f_{n*}(r^n \beta) = r^n f_{n*}(\beta) \in r^n \text{Ext}_R^1(M, N)$  for every  $n \geq 0$ , and so  $\alpha = 0$ , a contradiction.

The last assertion follows from the first and Lemma 7.9. □

In fact, the converse of Proposition 12.3 holds as well. The proof requires a few technical results and two auxiliary tools, which are useful in other contexts as well: the stable Hom and the Auslander transpose.

**12.4 Definition.** Let  $M$  and  $N$  be finitely generated modules over a commutative (Noetherian, as always) ring  $A$ . Denote by  $\mathfrak{P}(M, N)$  the submodule of  $A$ -homomorphisms from  $M$  to  $N$  that factor through a projective  $A$ -module, and put

$$\underline{\text{Hom}}_R(M, N) = \text{Hom}_R(M, N) / \mathfrak{P}(M, N).$$

We call  $\underline{\text{Hom}}_R(M, N)$  the *stable Hom module*. We also write  $\underline{\text{End}}_A(M)$  for  $\underline{\text{Hom}}_A(M, M)$  and refer to it as the *stable endomorphism ring*.

Observe that  $\mathfrak{P}(M, M)$  is a two-sided ideal of the (non-commutative) ring  $\text{End}_A(M)$ , so that  $\underline{\text{End}}_A(M)$  really is a ring. In particular, it is a quotient of  $\text{End}_A(M)$ , so the stable endomorphism ring is nc-local if the usual endomorphism ring is.

As with the usual Hom, the stable Hom module  $\underline{\text{Hom}}_A(M, N)$  is naturally a left  $\underline{\text{End}}_A(M)$ -module and a right  $\underline{\text{End}}_A(N)$ -module. We leave the straightforward check that these actions are well-defined to the reader.

**12.5 Remark.** Recall that we write  $M^*$  for  $\text{Hom}_R(M, R)$ . Note that  $\mathfrak{P}(M, N)$  is the image of the natural homomorphism

$$\rho_M^N: M^* \otimes_A N \longrightarrow \text{Hom}_R(M, N)$$

defined by  $\rho(f \otimes y)(x) = f(x)y$  for  $f \in M^*$ ,  $y \in N$ , and  $x \in M$ . In particular  $M$  is projective if and only if  $\rho_M^M$  is surjective.

The other auxiliary tool we need to construct AR sequences is just as easy to define, though we need some more detailed properties from it.

**12.6 Definition.** Let  $A$  be a ring and  $M$  a finitely generated  $A$ -module with projective presentation

$$(12.6.1) \quad P_1 \xrightarrow{\varphi} P_0 \longrightarrow M \longrightarrow 0.$$

The *Auslander transpose*  $\text{Tr} M$  of  $M$  is defined by

$$\text{Tr} M = \text{cok}(\varphi^* : P_0^* \longrightarrow P_1^*),$$

where  $(-)^* = \text{Hom}_A(-, A)$ . In other words,  $\text{Tr} M$  is defined by the exactness of the sequence

$$0 \longrightarrow M^* \longrightarrow P_1^* \xrightarrow{\varphi^*} P_0^* \longrightarrow \text{Tr} M \longrightarrow 0.$$

**12.7 Remarks.** The Auslander transpose depends, up to projective direct summands, only on  $M$ . That is, if  $\varphi' : P'_1 \longrightarrow P'_0$  is another projective presentation of  $M$ , then there are projective  $A$ -modules  $Q$  and  $Q'$  such that  $\text{cok} \varphi^* \oplus Q \cong \text{cok}(\varphi')^* \oplus Q'$ . In particular  $\text{Tr} M$  is only well-defined up to “stable equivalence.” However, we will work with  $\text{Tr} M$  as if it were well-defined, taking care only to apply it in situations where the ambiguity will not matter, such as the vanishing of  $\text{Ext}_A^i(\text{Tr} M, -)$  or  $\text{Tor}_i^A(\text{Tr} M, -)$  for  $i \geq 1$ .

It is easy to check that  $\text{Tr} P$  is projective if  $P$  is, and that  $\text{Tr}(M \oplus N) \cong \text{Tr} M \oplus \text{Tr} N$  up to projective direct summands. Furthermore, in (12.6.1)  $\varphi^*$  is a projective presentation of  $\text{Tr} M$ , and  $\varphi^{**} = \varphi$  canonically, so we have  $\text{Tr}(\text{Tr} M) = M$  up to projective summands for every finitely generated  $A$ -module  $M$ .

When  $A$  is a local (or graded) ring, we can give a more apparently intrinsic definition of  $\text{Tr} M$  by insisting that  $\varphi$  be a minimal presentation, i.e.

all the entries of a matrix representing  $\varphi$  lie in the maximal ideal. However, even then we will not have  $\text{Tr}(\text{Tr } M) = M$  on the nose in general, since the Auslander transpose of any free module will be zero.

Finally, one can check that  $\text{Tr}(-)$  commutes with arbitrary base change. For example, it commutes (up to projective summands, as always) with localization and passing to  $A/(x)$  for an arbitrary element  $x \in A$ .

The Auslander transpose is intimately related to the canonical biduality homomorphism  $\sigma_M: M \rightarrow M^{**}$ , defined by

$$\sigma_M(x)(f) = f(x)$$

for  $x \in M$  and  $f \in M^*$ . More generally, we have the following proposition.

**12.8 Proposition.** *Let  $M$  and  $N$  be finitely generated  $A$ -modules. Then there is an exact sequence*

$$0 \rightarrow \text{Ext}_A^1(\text{Tr } M, N) \rightarrow M \otimes_A N \xrightarrow{\sigma_M^N} \text{Hom}_A(M^*, N) \rightarrow \text{Ext}_A^2(\text{Tr } M, N) \rightarrow 0$$

in which  $\sigma_M^N$  is defined by  $\sigma_M^N(x \otimes y)(f) = f(x)y$  for  $x \in M$ ,  $y \in N$ , and  $f \in M^*$ . Moreover we have

$$\text{Ext}_A^i(\text{Tr } M, N) \cong \text{Ext}_A^{i-2}(M^*, N)$$

for all  $i \geq 3$ . In particular, taking  $N = A$  gives an exact sequence

$$0 \rightarrow \text{Ext}_A^1(\text{Tr } M, A) \rightarrow M \xrightarrow{\sigma_M} M^{**} \rightarrow \text{Ext}_A^2(\text{Tr } M, A) \rightarrow 0$$

and isomorphisms

$$\text{Ext}_A^i(\text{Tr } M, R) \cong \text{Ext}_A^{i-2}(M^*, R)$$

for  $i \geq 3$ .

We leave the proof as an exercise. The proposition motivates the following definition.

**12.9 Definition.** A finitely generated  $A$ -module  $M$  is called  $n$ -torsionless if  $\text{Ext}_A^i(\text{Tr } M, A) = 0$  for  $i = 1, \dots, n$ .

In particular,  $M$  is 1-torsionless if and only if  $\sigma_M: M \rightarrow M^{**}$  is injective, 2-torsionless if and only if  $M$  is reflexive, and  $n$ -torsionless for some  $n \geq 3$  if and only if  $M$  is reflexive and  $\text{Ext}_A^i(M^*, R) = 0$  for  $i = 1, \dots, n - 2$ .

**12.10 Proposition.** *Suppose that a finitely generated  $A$ -module  $M$  is  $n$ -torsionless. Then  $M$  is a  $n^{\text{th}}$  syzygy.*

*Proof.* For  $n = 0$  there is nothing to prove. For  $n = 1$ , let  $P \rightarrow M^*$  be a surjection with  $P$  projective; then the composition of the injections  $M \rightarrow M^{**}$  and  $M^{**} \rightarrow P^*$  shows that  $M$  is a submodule of a projective, whence a first syzygy. Similarly for  $n \geq 2$ , let  $P_{n-1} \rightarrow \dots \rightarrow P_0 \rightarrow M^* \rightarrow 0$  be a projective resolution of  $M^*$ . Dualizing and using the definition of  $n$ -torsionlessness, we see that

$$0 \rightarrow M \rightarrow P_0^* \rightarrow \dots \rightarrow P_{n-1}^*$$

is exact, so  $M$  is a  $n^{\text{th}}$  syzygy. □

**12.11 Proposition.** *Let  $R$  be a CM local ring of dimension  $d$ , and let  $M$  be a finitely generated  $R$ -module. Assume that  $R$  is Gorenstein on the punctured spectrum. Then the following are equivalent:*

- (i)  $M$  is MCM;
- (ii)  $M$  is a  $d^{\text{th}}$  syzygy;

(iii)  $M$  is  $d$ -torsionless, i.e.  $\text{Ext}_R^i(\text{Tr } M, R) = 0$  for  $i = 1, \dots, d$ .

*Proof.* Items (i) and (ii) are equivalent by Corollary A.17, since  $R$  is Gorenstein on the punctured spectrum. The implication (iii)  $\implies$  (ii) follows from the previous proposition. We have only to prove (i) implies (iii). So assume that  $M$  is MCM. The case  $d = 0$  is vacuous. For  $d = 1$ , the four-term exact sequence of Proposition 12.8 and the hypothesis that  $R$  is Gorenstein on the punctured spectrum combine to show that  $\text{Ext}_R^1(\text{Tr } M, R)$  has finite length. Since  $\text{Ext}_R^1(\text{Tr } M, R)$  embeds in  $M$  by Proposition 12.8 and  $M$  is torsion-free, this implies  $\text{Ext}_R^1(\text{Tr } M, R) = 0$ .

Now assume that  $d \geq 2$ . Let  $P_1 \rightarrow P_0 \rightarrow M \rightarrow 0$  be a free presentation of  $M$ , so that

$$0 \rightarrow M^* \rightarrow P_0^* \rightarrow P_1^* \rightarrow \text{Tr } M \rightarrow 0$$

is exact. Splice this together with a free resolution of  $M^*$  to get a resolution of  $\text{Tr } M$

$$G_{d+1} \xrightarrow{\varphi_{d+1}} G_d \xrightarrow{\varphi_d} \dots \xrightarrow{\varphi_3} G_2 \rightarrow P_0^* \rightarrow P_1^* \rightarrow \text{Tr } M \rightarrow 0.$$

Dualize, obtaining a complex

$$0 \rightarrow (\text{Tr } M)^* \rightarrow P_1 \rightarrow P_0 \rightarrow G_2^* \xrightarrow{\varphi_3^*} \dots \xrightarrow{\varphi_d^*} G_d^* \xrightarrow{\varphi_{d+1}^*} G_{d+1}^*$$

in which  $\ker \varphi_3^* \cong M$  since  $M$  is reflexive. The truncation of this complex at  $M$

$$(12.11.1) \quad 0 \rightarrow M \rightarrow G_2^* \xrightarrow{\varphi_3^*} \dots \xrightarrow{\varphi_d^*} G_d^* \xrightarrow{\varphi_{d+1}^*} G_{d+1}^*$$

is a complex of MCM  $R$ -modules, and since  $R$  is Gorenstein on the punctured spectrum, the homology  $\text{Ext}_R^{i-2}(M^*, R)$  has finite length. The Lemme

d'Acyclicité (Exercise 12.45) therefore implies that (12.11.1) is exact, so that  $M$  is a  $d^{\text{th}}$  syzygy.  $\square$

The most useful consequence of Proposition 12.11 from the point of view of AR theory is the following fact. Recall that we write  $\text{redsyz}_n^R(M)$  for the *reduced*  $n^{\text{th}}$  syzygy module, i.e. the module obtained by deleting any non-trivial free direct summands from the  $n^{\text{th}}$  syzygy module  $\text{syz}_n^R(M)$ . In particular  $\text{redsyz}_0^R(M)$  is gotten from  $M$  by deleting any free direct summands.

**12.12 Proposition.** *Let  $R$  be a CM local ring of dimension  $d$  and assume that  $R$  is Gorenstein on the punctured spectrum. Let  $M$  be an indecomposable non-free MCM  $R$ -module which is locally free on the punctured spectrum. Then  $\text{redsyz}_j^R(\text{Tr } M)$  is indecomposable for every  $j = 0, \dots, d$ .*

*Proof.* Fix a free presentation  $P_1 \xrightarrow{\varphi} P_0 \rightarrow M \rightarrow 0$  of  $M$ , so that  $\text{Tr } M$  appears in an exact sequence

$$0 \rightarrow M^* \rightarrow P_0^* \xrightarrow{\varphi^*} P_1^* \rightarrow \text{Tr } M \rightarrow 0.$$

First consider the case  $j = 0$ . It suffices to prove that if  $\text{Tr } M \cong X \oplus Y$  for  $R$ -modules  $X$  and  $Y$ , then one of  $X$  or  $Y$  is free. If  $\text{Tr } M \cong X \oplus Y$ , then  $\varphi^*$  can be decomposed as the direct sum of two matrices, that is,  $\varphi^*$  is equivalent to a matrix of the form  $\begin{bmatrix} \alpha \\ \beta \end{bmatrix}$  with  $X \cong \text{cok } \alpha$  and  $Y \cong \text{cok } \beta$ . But then  $M = \text{cok } \varphi \cong \text{cok } \alpha^* \oplus \text{cok } \beta^*$ . This forces one of  $\text{cok } \alpha$  or  $\text{cok } \beta$  to be zero, which means that one of  $X \cong \text{cok } \alpha^*$  or  $Y \cong \text{cok } \beta^*$  is free.

Next assume that  $j = 1$ , and let  $N$  be the image of  $\varphi^* : P_1^* \rightarrow P_0^*$ , so that  $N \cong \text{redsyz}_1^R(\text{Tr } M) \oplus G$  for some finitely generated free module  $G$ . Again it suffices to prove that if  $N \cong X \oplus Y$ , then one of  $X$  or  $Y$  is free. Let  $F$  be

a finitely generated free module mapping onto  $M^*$ , and let  $f: F \rightarrow P_0^*$  be the composition so that we have an exact sequence

$$F \xrightarrow{f} P_0^* \xrightarrow{\varphi^*} P_1^* \rightarrow \text{Tr } M \rightarrow 0.$$

The dual of this sequence is exact since  $\text{Ext}_R^1(\text{Tr } M, R) = 0$  by Proposition 12.11, so we obtain the exact sequence

$$P_1^{**} \xrightarrow{\varphi^{**}} P_0^{**} \xrightarrow{f^*} F^*$$

It follows that  $M \cong \text{cok } \varphi^{**} \cong \text{im } f^*$ . Now, if  $N = \text{cok } f$  decomposes as  $N \cong X \oplus Y$ , then  $f$  can be put in block-diagonal form  $\begin{bmatrix} \alpha & \\ & \beta \end{bmatrix}$ . It follows that  $M \cong \text{im } \alpha^* \oplus \text{im } \beta^*$ , so that one of  $\text{im } \alpha^*$  or  $\text{im } \beta^*$  is zero. This implies that one of  $X = \text{cok } \alpha$  or  $Y = \text{cok } \beta$  is free.

Now assume that  $j \geq 2$ , and we will show by induction on  $j$  that  $\text{redsyz}_j^R(\text{Tr } M)$  is indecomposable. Note that since  $d \geq 2$  and  $R$  is Gorenstein in codimension one,  $M$  is reflexive by Corollary A.15. Thus the case  $j = 2$  is clear: if  $\text{redsyz}_2^R(\text{Tr } M) = \text{redsyz}_0^R(M^*)$  decomposes, then so does  $M \cong M^{**}$ .

Assume  $2 < j < d$ , and that  $\text{redsyz}_{j-1}^R(\text{Tr } M)$  is indecomposable. Note that Corollary A.15 again implies that  $\text{redsyz}_{j-1}^R(\text{Tr } M)$  and  $\text{redsyz}_j^R(\text{Tr } M)$  are reflexive. We have an exact sequence

$$0 \rightarrow \text{redsyz}_j^R(\text{Tr } M) \oplus G \rightarrow F \rightarrow \text{redsyz}_{j-1}^R(\text{Tr } M) \rightarrow 0,$$

with  $F$  and  $G$  finitely generated free modules. By Proposition 12.11, we have

$$\text{Ext}_R^1(\text{redsyz}_{j-1}^R(\text{Tr } M), R) = \text{Ext}_R^j(\text{Tr } M, R) = 0,$$

so that the dual sequence

$$0 \rightarrow (\text{redsyz}_{j-1}^R(\text{Tr } M))^* \rightarrow F^* \rightarrow (\text{redsyz}_j^R(\text{Tr } M))^* \oplus G^* \rightarrow 0$$

is also exact. If  $\text{redsyz}_j^R(\text{Tr } M)$  decomposes as  $X \oplus Y$  with neither  $X$  nor  $Y$  free, then  $\text{syz}_1^R(X^*)$  and  $\text{syz}_1^R(Y^*)$  are direct summands of  $(\text{redsyz}_{j-1}^R(\text{Tr } M))^*$ . We know that  $X^*$  and  $Y^*$  are non-zero since both  $X$  and  $Y$  embed in a free module, and neither  $X^*$  nor  $Y^*$  is free by the reflexivity of  $\text{redsyz}_j^R(\text{Tr } M)$ . Thus  $(\text{redsyz}_{j-1}^R(\text{Tr } M))^*$  is decomposed non-trivially, so that  $\text{redsyz}_{j-1}^R(\text{Tr } M)$  is as well, a contradiction.  $\square$

Next we see how the Auslander transpose and stable Hom interact. Notice that for any  $A$ -module  $M$ ,  $\text{Tr } M$  is naturally a module over  $\text{End}_A(M)$ , since any endomorphism of  $M$  lifts to an endomorphism of its projective presentation, thus inducing an endomorphism of  $\text{Tr } M$ .

**12.13 Proposition.** *Let  $A$  be a commutative ring and  $M, N$  two finitely generated  $A$ -modules. Then*

$$\underline{\text{Hom}}_A(M, N) \cong \text{Tor}_1^A(\text{Tr } M, N).$$

*Furthermore, this isomorphism is natural in both  $M$  and  $N$ , and is even an isomorphism of  $\underline{\text{End}}_A(M)$ - and  $\underline{\text{End}}_A(N)$ -modules.*

*Proof.* Let  $P_1 \xrightarrow{\varphi} P_0 \rightarrow M \rightarrow 0$  be our chosen projective presentation of  $M$ . Then we have the exact sequence

$$0 \rightarrow M^* \rightarrow P_0^* \xrightarrow{\varphi^*} P_1^* \rightarrow \text{Tr } M \rightarrow 0.$$

Tensoring with  $N$  yields the complex

$$M^* \otimes_A N \rightarrow P_0^* \otimes_A N \xrightarrow{\varphi^* \otimes 1_N} P_1^* \otimes_A N \rightarrow \text{Tr } M \otimes_A N \rightarrow 0.$$

The homology of this complex at  $P_0^* \otimes_A N$  is identified as  $\text{Tor}_1^A(\text{Tr } M, N)$ . On the other hand, since the  $P_i$  are projective  $A$ -modules, the natural homomorphisms  $P_i^* \otimes_A N \rightarrow \text{Hom}_A(P_i^*, N)$  are isomorphisms (Exercise 12.46). It

follows that  $\ker(\varphi^* \otimes_A 1_N) \cong \text{Hom}_R(M, N)$ , and so  $\text{Tor}_1^A(\text{Tr } M, N)$  is isomorphic to the quotient of  $\text{Hom}_A(M, N)$  by the image of  $M^* \otimes_A N \rightarrow \text{Hom}_A(P_0, N)$ , namely  $\text{Tor}_1^A(\text{Tr } M, N) \cong \underline{\text{Hom}}_A(M, N)$ .

We leave the ‘‘Furthermore’’ to the reader. □

Our last preparation before showing the existence of AR sequences is a short sequence of technical lemmas. The first one has the appearance of a spectral sequence, but can be proven by hand just as easily, and we leave it to the reader.

**12.14 Lemma** ([CE99, VI.5.1]). *Let  $A$  be a commutative ring and  $X, Y, Z$   $A$ -modules. Then the Hom- $\otimes$  adjointness isomorphism*

$$\text{Hom}_A(X, \text{Hom}_A(Y, Z)) \longrightarrow \text{Hom}_A(X \otimes_A Y, Z)$$

*induces homomorphisms*

$$\text{Ext}_A^i(X, \text{Hom}_A(Y, Z)) \longrightarrow \text{Hom}_A(\text{Tor}_i^A(X, Y), Z)$$

*for every  $i \geq 0$ , which are isomorphisms if  $Z$  is injective.*

**12.15 Lemma.** *Let  $(R, \mathfrak{m}, k)$  be a CM local ring of dimension  $d$  with canonical module  $\omega$ . Let  $E = E_R(k)$  be the injective hull of the residue field of  $R$ . For any two  $R$ -modules  $X$  and  $Y$  such that  $Y$  is MCM and  $\text{Tor}_i^R(X, Y)$  has finite length for all  $i > 0$ , we have*

$$\text{Ext}_R^i(X, \text{Hom}_R(Y, E)) \cong \text{Ext}_R^{i+d}(X, \text{Hom}_R(Y, \omega)).$$

*Proof.* Let  $0 \rightarrow \omega \rightarrow I^0 \rightarrow \dots \rightarrow I^d \rightarrow 0$  be a (finite) injective resolution of  $\omega$ . Let  $\kappa(\mathfrak{p})$  denote the residue field of  $R_{\mathfrak{p}}$  for a prime ideal  $\mathfrak{p}$  of

$R$ . Since  $\text{Ext}_{R_{\mathfrak{p}}}^i(\kappa(\mathfrak{p}), \omega) = 0$  for  $i < \text{height } \mathfrak{p}$ , and is isomorphic to  $\kappa(\mathfrak{p})$  for  $i = \text{height } \mathfrak{p}$ , we see first that  $I^d \cong E$ , and second (by an easy induction) that  $\text{Hom}_R(L, I^j) = 0$  for every  $j < d$  and every  $R$ -module  $L$  of finite length.

Apply  $\text{Hom}_R(Y, -)$  to  $I^\bullet$ . Since  $Y$  is MCM,  $\text{Ext}_R^i(Y, \omega) = 0$  for  $i > 0$ , so the result is an exact sequence

$$(12.15.1) \quad 0 \longrightarrow \text{Hom}_R(Y, \omega) \longrightarrow \text{Hom}_R(Y, I^0) \longrightarrow \cdots \longrightarrow \text{Hom}_R(Y, I^d) \longrightarrow 0$$

Now from Lemma 12.14, we have

$$\text{Ext}_R^i(X, \text{Hom}_R(Y, I^j)) \cong \text{Hom}_R(\text{Tor}_i^R(X, Y), I^j)$$

for every  $i, j \geq 0$ . For  $i \geq 1$  and  $j < d$ , however, the right-hand side vanishes since  $\text{Tor}_i^R(X, Y)$  has finite length. Thus applying  $\text{Hom}_R(X, -)$  to (12.15.1), we may use the long exact sequence of Ext to find that

$$\text{Ext}_R^i(X, \text{Hom}_R(Y, I^d)) \cong \text{Ext}_R^i(X, \text{Hom}_R(Y, \omega)).$$

□

**12.16 Proposition.** *Let  $(R, \mathfrak{m}, k)$  be a CM local ring of dimension  $d$  with canonical module  $\omega$ . Let  $M$  and  $N$  be finitely generated  $R$ -modules with  $M$  locally free on the punctured spectrum and  $N$  MCM. Then there is an isomorphism*

$$\text{Hom}_R(\underline{\text{Hom}}_R(M, N), E_R(k)) \cong \text{Ext}_R^1(N, (\text{redsyz}_d^R(\text{Tr } M))^\vee),$$

where  $-\vee$  as usual denotes  $\text{Hom}_R(-, \omega)$ . This isomorphism is natural in  $M$  and  $N$ , and is even an isomorphism of  $\underline{\text{End}}_R(M)$ - and  $\underline{\text{End}}_R(N)$ -modules.

*Proof.* By Proposition 12.13, we have  $\underline{\text{Hom}}_R(M, N) \cong \text{Tor}_1^R(\text{Tr } M, N)$ . Making that substitution in the left-hand side and applying Lemma 12.14, we see

$$\begin{aligned} \text{Hom}_R(\underline{\text{Hom}}_R(M, N), E_R(k)) &\cong \text{Hom}_R(\text{Tor}_1^R(\text{Tr } M, N), E_R(k)) \\ &\cong \text{Ext}_R^1(\text{Tr } M, \text{Hom}_R(N, E_R(k))). \end{aligned}$$

By Lemma 12.15, this last is isomorphic to  $\text{Ext}_R^{d+1}(\text{Tr } M, \text{Hom}_R(N, \omega))$  since  $\ell(\text{Tor}_i^R(\text{Tr } M, N)) < \infty$  for all  $i \geq 1$ . Take a reduced  $d^{\text{th}}$  syzygy of  $\text{Tr } M$ , as foreshadowed by Proposition 12.12, to get  $\text{Ext}_R^1(\text{redsyzy}_d^R(\text{Tr } M), N^\vee)$ . Finally, canonical duality for the MCM modules  $\text{redsyzy}_d^R \text{Tr } M$  and  $N^\vee$  shows that this last module is naturally isomorphic to  $\text{Ext}_R^1(N, (\text{redsyzy}_d^R \text{Tr } M)^\vee)$ .

Again we leave the assertion about naturality to the reader. □

For brevity, from now on we write

$$\tau(M) = \text{Hom}_R(\text{redsyzy}_d^R \text{Tr } M, \omega)$$

and call it the *Auslander translate* of  $M$ .

**12.17 Theorem.** *Let  $(R, \mathfrak{m}, k)$  be a Henselian CM local ring of dimension  $d$  and let  $M$  be an indecomposable MCM  $R$ -module which is locally free on the punctured spectrum. Then there exists an AR sequence for  $M$*

$$\alpha: 0 \longrightarrow \tau(M) \longrightarrow E \longrightarrow M \longrightarrow 0.$$

*Precisely, the  $\underline{\text{End}}_R(M)$ -module  $\text{Ext}_R^1(M, \tau(M))$  has one-dimensional socle, and any representative for a generator for that socle is an AR sequence for  $M$ .*

*Proof.* First observe that  $\underline{\text{End}}_R(M)$  is a quotient of the nc-local ring  $\text{End}_R(M)$ , so is again nc-local. Thus the Matlis dual  $\text{Hom}_R(\underline{\text{End}}_R(M), E_R(k))$  has a one-dimensional socle. By Proposition 12.16, this Matlis dual is isomorphic to  $\text{Ext}_R^1(M, \tau(M))$ . Let  $\alpha: 0 \rightarrow \tau(M) \rightarrow E \rightarrow M \rightarrow 0$  be a generator for the socle of  $\text{Ext}_R^1(M, \tau(M))$ .

We know from Proposition 12.12 that  $\text{redsyzy}_d^R \text{Tr } M$  is indecomposable, so its canonical dual  $\tau(M)$  is indecomposable as well. It therefore suffices to check the lifting property. Let  $f: X \rightarrow M$  be a homomorphism of MCM  $R$ -modules. Then pullback along  $f$  induces a homomorphism  $f^*: \text{Ext}_R^1(M, \tau(M)) \rightarrow \text{Ext}_R^1(X, \tau(M))$ . If  $f$  does not factor through  $E$ , then the image of  $\alpha$  in  $\text{Ext}_R^1(X, \tau(M))$  is non-zero. Since  $\alpha$  generates the socle and  $\alpha$  does not go to zero, we see that in fact  $f^*$  must be injective. By Proposition 12.16, this injective homomorphism is the same as the one

$$\text{Hom}_R(\underline{\text{End}}_R(M), E_R(k)) \rightarrow \text{Hom}_R(\underline{\text{Hom}}(X, M), E_R(k))$$

induced by  $f: X \rightarrow M$ . Since  $f^*$  is injective, Matlis duality implies that

$$\underline{\text{Hom}}_R(X, M) \rightarrow \underline{\text{End}}_R(M)$$

is surjective. In particular, the map  $\text{Hom}_R(X, M) \rightarrow \text{End}_R(M)$  induced by  $f$  is surjective. It follows that  $f$  is a split surjection, so we are done.  $\square$

**12.18 Corollary.** *Let  $R$  be a Henselian CM local ring with canonical module, and assume that  $R$  is an isolated singularity. Then every indecomposable non-free MCM  $R$ -module has an AR sequence.*

## §2 AR quivers

The Auslander–Reiten quiver is a convenient scheme for packaging AR sequences. Up to first approximation, we could define it already: The AR quiver of a Henselian CM local ring with isolated singularity is the directed graph having a vertex  $[M]$  for each indecomposable non-free MCM module  $M$ , a dotted line joining  $[M]$  to  $[\tau(M)]$ , and an arrow  $[X] \rightarrow [M]$  for each occurrence of  $X$  in a direct-sum decomposition of the middle term of the AR sequence for  $M$ .

Unfortunately, this first approximation omits the indecomposable free module  $R$ . It is also manifestly asymmetrical: it takes into account only the AR sequences ending in a module, and omits those starting from a module. To remedy these defects, as well as for later use (particularly in Chapter 14), we introduce now irreducible homomorphisms between MCM modules, and use them to define the AR quiver. We then reconcile this definition with the naive one above, and check to see what additional information we've gained.

In this section,  $(R, \mathfrak{m}, k)$  is a Henselian CM local ring with canonical module  $\omega$ , and we assume that  $R$  has an isolated singularity.

**12.19 Definition.** Let  $M$  and  $N$  be MCM  $R$ -modules. A homomorphism  $\varphi: M \rightarrow N$  is called *irreducible* if it is neither a split injection nor a split surjection, and in any factorization

$$\begin{array}{ccc} M & \xrightarrow{\varphi} & N \\ & \searrow g & \nearrow h \\ & & X \end{array}$$

with  $X$  a MCM  $R$ -module, either  $g$  is a split injection or  $h$  is a split surjection.

Observe that the set of irreducible homomorphisms is not a submodule of  $\text{Hom}_R(M, N)$ . We can, however, describe it more precisely.

**12.20 Definition.** Let  $M$  and  $N$  be MCM  $R$ -modules.

- (i) Let  $\text{rad}(M, N) \subseteq \text{Hom}_R(M, N)$  be the submodule consisting of those homomorphisms  $\varphi: M \rightarrow N$  such that, when we decompose  $M = \bigoplus_j M_j$  and  $N = \bigoplus_i N_i$  into indecomposable modules, and accordingly decompose  $\varphi = (\varphi_{ij}: M_j \rightarrow N_i)_{ij}$ , no  $\varphi_{ij}$  is an isomorphism.
- (ii) Let  $\text{rad}^2(M, N) \subseteq \text{Hom}_R(M, N)$  be the submodule of those homomorphisms  $\varphi: M \rightarrow N$  for which there is a factorization

$$\begin{array}{ccc}
 M & \xrightarrow{\varphi} & N \\
 & \searrow \alpha & \nearrow \beta \\
 & X &
 \end{array}$$

with  $X$  MCM,  $\alpha \in \text{rad}(M, X)$  and  $\beta \in \text{rad}(X, N)$ .

**12.21 Remark.** Suppose that  $M$  and  $N$  are indecomposable. If  $M$  and  $N$  are not isomorphic, then  $\text{rad}(M, N)$  is simply  $\text{Hom}_R(M, N)$ . If, on the other hand,  $M \cong N$ , then  $\text{rad}(M, N)$  is the Jacobson radical of the nc-local ring  $\text{End}_R(M)$ , whence the name. In particular  $\mathfrak{m} \text{End}_R(M) \subseteq \text{rad}(M, M)$  by Lemma 1.7.

For any  $M$  and  $N$ , not necessarily indecomposable, it's clear that the set of irreducible homomorphisms from  $M$  to  $N$  coincides with  $\text{rad}(M, N) \setminus \text{rad}^2(M, N)$ . Furthermore we have  $\mathfrak{m} \text{rad}(M, N) \subseteq \text{rad}^2(M, N)$  (Exercise 12.48), so that the following definition makes sense.

**12.22 Definition.** Let  $M$  and  $N$  be MCM  $R$ -modules, and put

$$\text{Irr}(M, N) = \text{rad}(M, N) / \text{rad}^2(M, N).$$

Denote by  $\text{irr}(M, N)$  the  $k$ -vector space dimension of  $\text{Irr}(M, N)$ .

Now we are ready to define the AR quiver of  $R$ . We impose an additional hypothesis on  $R$ , that the residue field  $k$  be algebraically closed.

**12.23 Definition.** Let  $(R, \mathfrak{m}, k)$  be a Henselian CM local ring with a canonical module. Assume that  $R$  has an isolated singularity and that  $k$  is algebraically closed. The *Auslander-Reiten (AR) quiver* for  $R$  is the graph  $\Gamma$  with

- vertices  $[M]$  for each indecomposable MCM  $R$ -module  $M$ ;
- $r$  arrows from  $[M]$  to  $[N]$  if  $\text{irr}(M, N) = r$ ; and
- a dotted (undirected) line between  $[M]$  and its AR translate  $[\tau(M)]$  for every  $M$ .

Without the assumption that  $k$  be algebraically closed, we would need to define the AR quiver as a *valued* quiver, as follows. Suppose  $[M]$  and  $[N]$  are vertices in  $\Gamma$ , and that there is an irreducible homomorphism  $M \rightarrow N$ . The abelian group  $\text{Irr}(M, N)$  is naturally a  $\text{End}_R(N)$ - $\text{End}_R(M)$  bimodule, with the left and right actions inherited from those on  $\text{Hom}_R(M, N)$ . As such, it is annihilated by the radical of each endomorphism ring (see again Exercise 12.48). Let  $m$  be the dimension of  $\text{Irr}(M, N)$  as a right vector space over  $\text{End}_R(M) / \text{rad}(M, M)$ , and symmetrically let  $n$  be the dimension of  $\text{Irr}(M, N)$  over  $\text{End}_R(N) / \text{rad}(N, N)$ . Then we would draw an arrow from

$[M]$  to  $[N]$  in  $\Gamma$ , and decorate it with the ordered pair  $(m, n)$ . In the special case of an algebraically closed field  $k$ ,  $\text{End}_R(M)/\text{rad}(M, M)$  is in fact isomorphic to  $k$  for every indecomposable  $M$ , so we always have  $m = n$ .

We now reconcile the definition of the AR quiver with our earlier naive version, which included only the non-free indecomposable MCM modules.

**12.24 Proposition.** *Let  $0 \rightarrow N \xrightarrow{i} E \xrightarrow{p} M \rightarrow 0$  be an AR sequence. Then  $i$  and  $p$  are irreducible homomorphisms.*

*Proof.* We prove only the assertion about  $p$ , since the other is exactly dual. First we claim that  $p$  is *right minimal*, that is (see Definition 11.11), that whenever  $\varphi: E \rightarrow E$  is an endomorphism such that  $p\varphi = p$ , in fact  $\varphi$  is an automorphism. The proof of this is similar to that of Proposition 12.2: the existence of  $\varphi \in \text{End}_R(E)$  such that  $p\varphi = p$  defines a commutative diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & N & \xrightarrow{i} & E & \xrightarrow{p} & M & \longrightarrow & 0 \\ & & \psi \downarrow & & \varphi \downarrow & & \parallel & & \\ 0 & \longrightarrow & N & \xrightarrow{i} & E & \xrightarrow{p} & M & \longrightarrow & 0 \end{array}$$

of exact sequences, where  $\psi$  is the restriction of  $\varphi$  to  $N$ . To see that  $\varphi$  is an isomorphism, it suffices by the Snake Lemma to show that  $\psi$  is an isomorphism. If not, then (since  $N$  is indecomposable and  $\text{End}_R(N)$  is therefore nc-local)  $1_N - \psi$  is an isomorphism. Then  $(1_E - \varphi): E \rightarrow N$  restricts to an isomorphism on  $N$  and therefore splits the AR sequence. This contradiction proves the claim.

We now show  $p$  is irreducible. Assume that we have a factorization

$$\begin{array}{ccc} E & \xrightarrow{p} & M \\ & \searrow f & \nearrow g \\ & & X \end{array}$$

in which  $g$  is not a split surjection. The lifting property of AR sequences delivers a homomorphism  $u: X \rightarrow E$  such that  $g = pu$ . Thus we obtain a larger commutative diagram

$$\begin{array}{ccccc} E & \xrightarrow{f} & X & \xrightarrow{u} & E \\ & \searrow p & \downarrow g & \swarrow p & \\ & & M & & \end{array}$$

Since  $p$  is right minimal by the claim,  $uf$  is an automorphism of  $E$ . In particular,  $f$  is a split injection.  $\square$

Recall that we write  $A \mid B$  to mean that  $A$  is isomorphic to a direct summand of  $B$ .

**12.25 Proposition.** *Let  $0 \rightarrow N \xrightarrow{i} E \xrightarrow{p} M \rightarrow 0$  be an AR sequence.*

- (i) *A homomorphism  $\varphi: X \rightarrow M$  is irreducible if and only if  $\varphi$  is a direct summand of  $p$ . Explicitly, this means that  $X \mid E$  and  $\varphi$  factors through the inclusion  $j$  of  $X$  as a direct summand of  $E$ , that is,  $\varphi = pj$  for a split injection  $j$ .*
- (ii) *A homomorphism  $\psi: N \rightarrow Y$  is irreducible if and only if  $\psi$  is a direct summand of  $i$ . This means  $Y \mid E$  and  $\psi$  lifts over the projection  $\pi$  of  $E$  onto  $Y$ , that is,  $\psi = \pi i$  for a split surjection  $\pi$ .*

*Proof.* Again we prove only the first part and leave the dual to the reader.

Assume first that  $\varphi: X \rightarrow M$  is irreducible. The lifting property of AR sequences gives a factorization  $\varphi = pj$  for some  $j: X \rightarrow E$ . Since  $\varphi$  is irreducible and  $p$  is not a split surjection,  $j$  is a split injection.

For the converse, assume that  $E \cong X \oplus X'$ , and write  $p = [\alpha \ \beta]: X \oplus X' \rightarrow M$  along this decomposition. We must show that  $\alpha$  is irreducible. First observe that neither  $\alpha$  nor  $\beta$  is a split surjection, since  $p$  is not. If, now, we have a factorization

$$\begin{array}{ccc} X & \xrightarrow{\alpha} & M \\ & \searrow g & \nearrow h \\ & Z & \end{array}$$

with  $Z$  MCM and  $h$  not a split surjection, then we obtain a diagram

$$\begin{array}{ccc} X \oplus X' & \xrightarrow{[\alpha \ \beta]} & M \\ & \searrow \begin{bmatrix} g & 0 \\ 0 & 1_{X'} \end{bmatrix} & \nearrow [h \ \beta] \\ & Z \oplus X' & \end{array}$$

As  $p = [\alpha \ \beta]$  is irreducible by Proposition 12.24, and  $[h \ \beta]$  is not a split surjection by Exercise 1.23, we find that  $g$  is a split injection.  $\square$

**12.26 Corollary.** *Let  $0 \rightarrow N \rightarrow E \rightarrow M \rightarrow 0$  be an AR sequence. Then for any indecomposable MCM  $R$ -module  $X$ ,  $\text{irr}(N, X) = \text{irr}(X, M)$  is the multiplicity of  $X$  in the decomposition of  $E$  as a direct sum of indecomposables.*

Now we deal with  $[R]$ .

**12.27 Proposition.** *Let  $(R, \mathfrak{m})$  be a Henselian local ring with a canonical module, and assume that  $R$  has an isolated singularity. Let  $0 \rightarrow Y \rightarrow X \xrightarrow{q} \mathfrak{m} \rightarrow 0$  be the minimal MCM approximation of the maximal ideal  $\mathfrak{m}$ . (If  $\dim R \leq 1$ , we take  $X = \mathfrak{m}$  and  $Y = 0$ .) Then a homomorphism  $\varphi: M \rightarrow R$  with  $M$  MCM is irreducible if and only if  $\varphi$  is a direct summand of  $q$ . In other words,  $\varphi$  is irreducible if and only if  $M \mid X$  and  $\varphi$  factors through the inclusion of  $M$  as a direct summand of  $X$ , that is,  $\varphi = qj$  for some split injection  $j$ .*

*Proof.* Assume that  $\varphi: M \rightarrow R$  is irreducible. Since  $\varphi$  is not a split surjection, the image of  $\varphi$  is contained in  $\mathfrak{m}$ . We can therefore lift  $\varphi$  to factor through  $q$ , obtaining a factorization  $M \xrightarrow{j} X \xrightarrow{q} \mathfrak{m}$ . This factorization composes with the inclusion of  $\mathfrak{m}$  into  $R$  to give a factorization of  $\varphi: M \xrightarrow{j} X \rightarrow R$ . Since  $\varphi$  is irreducible and  $X \rightarrow R$  is not surjective,  $j$  is a split injection.  $\square$

**12.28 Remark.** Putting Propositions 12.25 and 12.27 together, we find in particular that the AR quiver is *locally finite*, i.e. each vertex has only finitely many arrows incident to it. The local structure of the quiver is

where  $N = \tau(M)$  and  $E = \bigoplus_{i=1}^s E_i$  is the middle term of the AR sequence ending in  $M$ .

### §3 Examples

**12.29 Example.** We can compute the AR quiver for a power series ring  $R = k[[x_1, \dots, x_d]]$  directly. It has a single vertex,  $[R]$ , and the irreducible homomorphisms  $R \rightarrow R$  are by Proposition 12.27 and Exercise 11.44 the direct summands of  $R^{(d)} \xrightarrow{[x_1 \ \dots \ x_d]} R$ , the beginning of the Koszul resolution

of  $\mathfrak{m} = (x_1, \dots, x_d)$ . Thus  $\text{irr}(R, R) = d$  and

$$[R] \begin{array}{c} \curvearrowright \\ \curvearrowleft \end{array} d$$

is the AR quiver. Note alternatively that  $\mathfrak{m} = \text{rad}(R, R)$ , while  $\mathfrak{m}^2 = \text{rad}^2(R, R)$ , and  $d = \dim_k(\mathfrak{m}/\mathfrak{m}^2)$ .

**12.30 Example.** We can also compute directly the AR quiver for the two-dimensional ( $A_1$ ) singularity  $k[[x, y, z]]/(xz - y^2)$ , though this one is less trivial. By Example 5.25, there is a single non-free indecomposable MCM module, namely the ideal

$$I = (x, y)R \cong \text{cok} \left( \begin{bmatrix} y & -x \\ -z & y \end{bmatrix}, \begin{bmatrix} y & x \\ z & y \end{bmatrix} \right).$$

We compute  $\text{Irr}(I, I)$  from the definition: we have  $\text{Hom}_R(I, I) \cong R$  since  $R$  is integrally closed, so that  $\text{rad}(I, I) = \mathfrak{m}$ , the maximal ideal  $(x, y, z)$ . Furthermore, for any element  $f \in \mathfrak{m}$ , the endomorphism of  $I$  given by multiplication by  $f$  factors through  $R^{(2)}$ . Indeed,  $I$  is isomorphic to the submodule of  $R^{(2)}$  generated by the column vectors  $\begin{pmatrix} y \\ x \end{pmatrix}$  and  $\begin{pmatrix} z \\ y \end{pmatrix}$ . If  $f = ax + by + cz$ , then the diagram

$$\begin{array}{ccc} I & \xrightarrow{ax+by+cz} & I \\ & \searrow & \nearrow \varphi \\ & R^{(2)} & \end{array}$$

commutes, where  $\varphi$  is defined by  $\varphi(e_1) = \begin{pmatrix} ax+cy \\ cy \end{pmatrix}$  and  $\varphi(e_2) = \begin{pmatrix} bz \\ ax+by \end{pmatrix}$ . Therefore  $\text{rad}^2(I, I) = \mathfrak{m} = \text{rad}(I, I)$  and  $\text{Irr}(I, I) = 0$ .

It follows that in the AR sequence ending in  $I$ ,

$$0 \longrightarrow \tau(I) \longrightarrow E \longrightarrow I \longrightarrow 0,$$

$E$  has no direct summands isomorphic to  $I$ , so is necessarily free. Since  $\tau(I) = (\text{redsyz}_2^R(\text{Tr } I))^\vee = (I^*)^\vee = I$ , the AR sequence is of the form

$$0 \longrightarrow I \longrightarrow R^{(2)} \longrightarrow I \longrightarrow 0,$$

and is the beginning of the free resolution of  $I$ . We conclude that the AR quiver of  $R$  is

$$[R] \begin{array}{c} \xrightarrow{\quad} \\ \xrightarrow{\quad} \\ \xleftarrow{\quad} \\ \xleftarrow{\quad} \end{array} [I].$$

The direct approach of Example 12.30 is impractical in general, but we can use the material of Chapters 5 and 6 to compute the AR quivers of the complete Kleinian singularities  $(A_n)$ ,  $(D_n)$ ,  $(E_6)$ ,  $(E_7)$ , and  $(E_8)$  of Table 6.2. They are isomorphic to the McKay–Gabriel quivers of the associated finite subgroups of  $\text{SL}(2, k)$ .

Recall the setup and definition of the McKay–Gabriel quiver in dimension two. Let  $k$  be a field and  $V = ku + kv$  a two-dimensional  $k$ -vector space. Let  $G \subseteq \text{GL}(V) \cong \text{GL}(2, k)$  be a finite group with order invertible in  $k$ , and assume that  $G$  acts on  $V$  with no non-trivial pseudo-reflections. In this situation the  $k$ -representations of  $G$ , the projective modules over the twisted group ring  $S\#G$ , and the MCM  $R$ -modules are equivalent as categories by Corollaries 5.20 and 6.4 and Theorem 6.3. Explicitly, the functor defined by  $W \mapsto S \otimes_k W$  is an equivalence between the finite-dimensional representations of  $G$  and the finitely generated projective  $S\#G$ -modules, while the functor given by  $P \mapsto P^G$  gives an equivalence between the latter category and  $\text{add}_R(S)$ , the  $R$ -direct summands of  $S$ . Since  $\dim V = 2$ , these are all the MCM  $R$ -modules by Theorem 6.3.

Writing  $V_0 = k, V_1, \dots, V_d$  for a complete set of non-isomorphic irreducible representations of  $G$ , we set

$$P_j = S \otimes_k V_j \quad \text{and} \quad M_j = (S \otimes_k V_j)^G$$

for  $j = 0, \dots, d$ . Then  $P_0 = S, P_1, \dots, P_d$  are the indecomposable finitely generated projective  $S\#G$ -modules, and  $M_0 = R, M_1, \dots, M_d$  are the indecomposable MCM  $R$ -modules.

The McKay–Gabriel quiver  $\Gamma$  for  $G$  (see Definitions 5.21 and 5.22 and Theorem 5.23) has for vertices the indecomposable projective  $S\#G$ -modules  $P_0, \dots, P_d$ . For each  $i$  and  $j$ , we draw  $m_{ij}$  arrows  $P_i \rightarrow P_j$  if  $V_i$  appears with multiplicity  $m_{ij}$  in the irreducible decomposition of  $V \otimes_k V_j$ .

**12.31 Proposition.** *With notation as above, the McKay–Gabriel quiver is isomorphic to the AR quiver of  $R = S^G$ . (We ignore the Auslander translate  $\tau$ .)*

*Proof.* First observe that  $R$  is a two-dimensional normal domain, whence an isolated singularity, so that AR quiver of  $R$  is defined.

It follows from Corollaries 5.20 and 6.4 and Theorem 6.3, as in the discussion above, that the equivalence of categories defined by

$$P_j = S \otimes_k V_j \quad \mapsto \quad M_j = (S \otimes_k V_j)^G$$

induces a bijection between the vertices of the McKay–Gabriel quiver and those of the AR quiver. It remains to determine the arrows.

Consider the Koszul complex over  $S$

$$0 \longrightarrow S \otimes_k \bigwedge^2 V \longrightarrow S \otimes_k V \longrightarrow S \longrightarrow k \longrightarrow 0,$$

which is also an exact sequence of  $S\#G$ -modules, and tensor with  $V_j$  to obtain

$$(12.31.1) \quad 0 \longrightarrow S \otimes_k \left( \bigwedge^2 V \otimes_k V_j \right) \longrightarrow S \otimes_k (V \otimes_k V_j) \longrightarrow P_j \longrightarrow V_j \longrightarrow 0.$$

Since  $\bigwedge^2 V$  has  $k$ -dimension 1, we see that  $\bigwedge^2 V \otimes_k V_j$  is a simple  $k[G]$ -module, so  $S \otimes_k (\bigwedge^2 V \otimes_k V_j)$  is an indecomposable projective  $S\#G$ -module. Take fixed points; since each  $V_j$  is simple, we have  $V_j^G = 0$  for all  $j \neq 0$ , and  $V_0^G = k^G = k$ . We obtain exact sequences of  $R$ -modules

$$(12.31.2) \quad 0 \longrightarrow \left( S \otimes_k \left( \bigwedge^2 V \otimes_k V_j \right) \right)^G \longrightarrow (S \otimes_k (V \otimes_k V_j))^G \xrightarrow{p_j} M_j \longrightarrow 0$$

for each  $j \neq 0$ , and

$$(12.31.3) \quad 0 \longrightarrow \left( S \otimes_k \bigwedge^2 V \right)^G \longrightarrow (S \otimes_k V)^G \xrightarrow{p_0} R \longrightarrow k \longrightarrow 0$$

for  $j = 0$ .

We now claim that (12.31.2) is the AR sequence ending in  $M_j$  for all  $j = 1, \dots, d$ , while the map  $p_0$  in (12.31.3) is the minimal MCM approximation of the maximal ideal of  $R$ . It will then follow from Propositions 12.25 and 12.27 that the number of arrows  $[M_i] \longrightarrow [M_j]$  in the AR quiver is equal to the multiplicity of  $M_i$  in a direct-sum decomposition of  $(S \otimes_k (V \otimes_k V_j))^G$ , which is equal to the multiplicity of  $V_i$  in the direct-sum decomposition of  $V \otimes_k V_j$ .

First assume that  $j \neq 0$ . We observed already that  $S \otimes_k (\bigwedge^2 V \otimes_k V_j)$  is an indecomposable projective  $S\#G$ -module, whence its fixed submodule  $(S \otimes_k (\bigwedge^2 V \otimes_k V_j))^G$  is an indecomposable MCM  $R$ -module. Since (12.31.1) is not split,  $p_j$  is non-split as well. Assume that  $X$  is a MCM  $R$ -module and

$f: X \rightarrow M_j$  is a homomorphism that is not a split surjection. There then exists a homomorphism of projective  $S\#G$ -modules  $\tilde{f}: \tilde{X} \rightarrow P_j$ , also not a split surjection, such that  $\tilde{X}^G = X$  and  $\tilde{f}^G = f$ . This fits into a diagram

$$\begin{array}{ccccccc}
 & & & \tilde{X} & & & \\
 & & & \downarrow \tilde{f} & & & \\
 S \otimes_k (V \otimes_k V_j) & \xrightarrow{\tilde{p}_j} & S \otimes_k V_j & \longrightarrow & V_j & \longrightarrow & 0.
 \end{array}$$

Since the image of  $f: X \rightarrow M_j$  is contained in that of  $p_j: (S \otimes_k (V \otimes_k V_j))^G \rightarrow M_j$ , the image of  $\tilde{f}$  is contained in that of  $\tilde{p}_j$ . But  $\tilde{X}$  is projective, so there exists  $\tilde{g}: \tilde{X} \rightarrow S \otimes_k (V \otimes_k V_j)$  such that  $\tilde{f} = \tilde{p}_j \tilde{g}$ . Set  $g = \tilde{g}^G$ ; then  $f = p_j g$ , proving the claim in this case.

For  $j = 0$ , the argument is essentially the same; if  $f: X \rightarrow \mathfrak{m}$  is any homomorphism from a MCM  $R$ -module  $X$  to the maximal ideal of  $R$ , then the composition  $X \rightarrow \mathfrak{m} \rightarrow R$  lifts to a homomorphism  $\tilde{f}: \tilde{X} \rightarrow S$  of projective  $S\#G$ -modules. The image of  $\tilde{f}$  is contained in the image of  $\tilde{p}_0: S \otimes_k V \rightarrow S$ , so again there exists  $\tilde{g}: \tilde{X} \rightarrow S \otimes_k V$  making the obvious diagram commute, and  $f$  factors through  $p_0$ .  $\square$

It follows from Proposition 12.31 and §3 of Chapter 6 that the AR quivers for the Kleinian singularities  $(A_n)$ ,  $(D_n)$ ,  $(E_6)$ ,  $(E_7)$ , and  $(E_8)$  are (after replacing pairs of opposing arrows by undirected edges) the corresponding extended ADE diagrams listed in Table 6.2. Indeed, we need not even worry about the Auslander translate  $\tau$ : since  $R$  is Gorenstein of dimension two,  $\tau(X) = (\text{redsyz}_R^d(\text{Tr } X))^\vee \cong X$  for every MCM  $X$ .

Glancing back at Example 5.25, we can write down a few more AR quivers. For instance, let  $R = k[[u^5, u^2v, uv^3, v^5]]$ , the fixed ring of the cyclic

group of order 5 generated by  $\text{diag}(\zeta_5, \zeta_5^3)$ . The AR quiver looks like

where

$$M_1 = R(u^4, uv, v^3) \cong (u^5, u^2v, uv^3)$$

$$M_2 = R(u^3, v) \cong (u^5, u^2v)$$

$$M_3 = R(u^2, uv^2, v^4) \cong (u^5, u^4v^2, u^3v^4)$$

$$M_4 = R(u, v^2) \cong (u^5, u^4v^2).$$

For another example, let  $R = k[[u^8, u^3v, uv^3, v^8]]$ . The AR quiver is

where this time

$$\begin{aligned}
 M_1 &= R(u^7, u^2v, v^3) \cong (u^8, u^3v, uv^3) \\
 M_2 &= R(u^6, uv, v^6) \cong (u^8, u^3v, u^2v^6) \\
 M_3 &= R(u^5, v) \cong (u^8, u^3v) \\
 M_4 &= R(u^4, u^2v^2, v^4) \cong (u^8, u^6v^2, u^4v^4) \\
 M_5 &= R(u^3, uv^2, v^7) \cong (u^8, u^6v^2, u^5v^7) \\
 M_6 &= R(u^2, u^5v, v^2) \cong (u^2v^6, u^5v^7, v^8) \\
 M_7 &= R(u, v^5) \cong (uv^3, v^8).
 \end{aligned}$$

Before leaving the case of dimension two, we briefly describe how to compute the AR quiver for an arbitrary two-dimensional normal domain which is not necessarily a ring of invariants. The short exact sequence (12.31.3)

$$0 \longrightarrow \left( S \otimes_k \bigwedge^2 V \right)^G \longrightarrow (S \otimes_k V)^G \xrightarrow{p_0} R \longrightarrow k \longrightarrow 0$$

appearing in the proof of Proposition 12.31 is called the *fundamental sequence for R*, and contains within it all the information carried by the entire AR quiver, as the proof of Proposition 12.31 shows. There is an analog of this sequence for general two-dimensional normal domains.

Assume that  $(R, \mathfrak{m}, k)$  is a complete local normal domain of dimension 2. Let  $\omega$  be the canonical module for  $R$ . Then we know that  $\text{Ext}_R^2(k, \omega) = k$ , so there is up to isomorphism a unique four-term exact sequence of the form

$$0 \longrightarrow \omega \xrightarrow{a} E \xrightarrow{b} R \longrightarrow k \longrightarrow 0$$

representing a non-zero element of  $\text{Ext}_R^2(k, \omega)$ . Call this the *fundamental sequence for R*. The module  $E$  is easily seen to be MCM of rank 2.

Let  $f: X \rightarrow R$  be a homomorphism of MCM  $R$ -modules which is not a split surjection. Then the image of  $f$  is contained in  $\mathfrak{m} = \text{im } b$ , and since  $\text{Ext}_R^1(X, \omega) = 0$ , the pullback diagram

$$\begin{array}{ccccccc} 0 & \longrightarrow & \omega & \longrightarrow & Q & \longrightarrow & X \longrightarrow 0 \\ & & \parallel & & \downarrow & & \downarrow f \\ 0 & \longrightarrow & \omega & \xrightarrow{a} & E & \xrightarrow{b} & R \end{array}$$

has split-exact top row. It follows that  $f$  factors through  $b: E \rightarrow R$ , so that  $b$  is a minimal MCM approximation of the maximal ideal  $\mathfrak{m}$ .

More is true. Recall from Exercise 6.46 that for reflexive (MCM)  $R$ -modules  $A$  and  $B$ , the reflexive product  $A \cdot B$  is defined by  $A \cdot B = (A \otimes_R B)^{**}$ .

**12.32 Theorem** ([Aus86b]). *Let  $(R, \mathfrak{m}, k)$  be a two-dimensional complete local normal domain with canonical module  $\omega$ . Let*

$$0 \longrightarrow \omega \longrightarrow E \longrightarrow R \longrightarrow k \longrightarrow 0$$

*be the fundamental sequence for  $R$ , and let  $M$  be an indecomposable non-free MCM  $R$ -module. Then the induced sequence*

$$(12.32.1) \quad 0 \longrightarrow \omega \cdot M \longrightarrow E \cdot M \longrightarrow M \longrightarrow 0$$

*is exact. If (12.32.1) is non-split, then it is the AR sequence ending in  $M$ . In particular, if  $\text{rank } M$  is a unit in  $R$ , then (12.32.1) is non-split, so is an AR sequence. The converse is true if  $k$  is algebraically closed.*

Let us return to the ADE singularities. The AR quivers for the one-dimensional ADE hypersurface singularities can also be obtained from those

in dimension two, together with the explicit matrix factorizations for the indecomposable MCM modules listed in §4 of Chapter 6.

For example, consider the one-dimensional ( $E_6$ ) singularity  $R = k[[x, y]](x^3 + y^4)$ , where  $k$  is a field of characteristic not 2, 3, or 5. Let  $R^\# = k[[x, y, z]]/(x^3 + y^4 + z^2)$  be the double branched cover. The matrix factorizations for the indecomposable MCM  $R^\#$ -modules are all of the form  $(zI_n - \varphi, zI_n + \varphi)$ , where  $\varphi$  is one of the matrices  $\varphi_1, \varphi_2, \varphi_3, \bar{\varphi}_3, \varphi_4,$  or  $\bar{\varphi}_4$  of 9.22. Flattening those matrix factorizations, i.e. killing  $z$ , amounts to ignoring  $z$  entirely and focusing simply on the  $\varphi_j$ . When we do this, certain of the matrix factorizations split into non-isomorphic pairs (as indicated by the block format of the matrices), while certain other pairs of matrix factorizations collapse into a single isomorphism class.

Specifically, we can see that  $\varphi_1$  splits into two non-equivalent matrices

$$\left( \begin{bmatrix} x & y^3 \\ y & -x^2 \end{bmatrix}, \begin{bmatrix} x^2 & y^3 \\ y & -x \end{bmatrix} \right)$$

forming a matrix factorization, and  $\varphi_2$  splits similarly into the matrix factorization

$$\left( \begin{bmatrix} x & 0 & y^2 \\ y & x & 0 \\ 0 & 0 & x \end{bmatrix}, \begin{bmatrix} x^2 & y^3 & -xy^2 \\ -xy & x^2 & y^3 \\ y^2 & -xy & x^2 \end{bmatrix} \right).$$

On the other hand, over  $R$ ,

$$\varphi_3 = \begin{bmatrix} iy^2 & 0 & -x^2 & 0 \\ 0 & iy^2 & -xy & -x^2 \\ x & 0 & -iy^2 & 0 \\ -y & x & 0 & -iy^2 \end{bmatrix} \quad \text{and} \quad \bar{\varphi}_3 = \begin{bmatrix} -iy^2 & 0 & -x^2 & 0 \\ 0 & -iy^2 & -xy & -x^2 \\ x & 0 & iy^2 & 0 \\ -y & x & 0 & iy^2 \end{bmatrix}$$

have isomorphic cokernels, as do

$$\varphi_4 = \begin{bmatrix} iy^2 & -x^2 \\ x & -iy^2 \end{bmatrix} \quad \text{and} \quad \bar{\varphi}_4 = \begin{bmatrix} -iy^2 & -x^2 \\ x & iy^2 \end{bmatrix}.$$

Therefore  $R$  has 6 non-isomorphic non-free indecomposable MCM modules, namely

$$M_{1a} = \text{cok} \begin{bmatrix} x & y^3 \\ y & -x^2 \end{bmatrix}, \quad M_{1b} = \text{cok} \begin{bmatrix} x^2 & y^3 \\ y & -x \end{bmatrix},$$

$$M_{2a} = \text{cok} \begin{bmatrix} x & 0 & y^2 \\ y & x & 0 \\ 0 & 0 & x \end{bmatrix}, \quad M_{2b} = \text{cok} \begin{bmatrix} x^2 & y^3 & -xy^2 \\ -xy & x^2 & y^3 \\ y^2 & -xy & x^2 \end{bmatrix}$$

$$M_3 = \text{cok} \varphi_3 = \text{cok} \bar{\varphi}_3$$

$$M_4 = \text{cok} \varphi_4 = \text{cok} \bar{\varphi}_4.$$

Since each of these modules is self-dual and the Auslander translate  $\tau$  is given by  $(\text{redsyz}_1^R(-^*))^*$ , we have  $\tau(M_{1a}) = M_{1b}$ ,  $\tau(M_{2a}) = M_{2b}$ , and vice versa, while  $\tau$  fixes  $M_3$  and  $M_4$ . One can compute the irreducible homomorphisms among these modules and obtain the AR quiver

where  $\tau$  is given by reflection across the horizontal axis.

For completeness, we list the AR quivers for all the one-dimensional ADE singularities below.

**12.33.** The extended  $(A_n)$  Coxeter-Dynkin diagram has  $n + 1$  nodes. The splitting/collapsing behavior of the matrix factorizations depends on the parity of  $n$ . When  $n = 2m$  is even, we find

with  $m + 1$  vertices. The Auslander translate  $\tau$  is the identity. When  $n = 2m + 1$  is odd, the quiver is

with  $m + 2$  vertices. Here  $\tau$  is reflection across the horizontal axis.

**12.34.** The extended  $(D_n)$  diagram also has  $n + 1$  nodes, and again the quiver depends on the parity of  $n$ . When  $n = 2m$  is even, every non-free MCM module splits, and the quiver looks like

with  $4m + 1$  vertices. The translate  $\tau$  is given by reflection in the horizontal axis for those vertices not on the axis, swaps  $a$  and  $d$ , and swaps  $b$  and  $c$ . When  $n = 2m + 1$  is odd, the two “legs” at the opposite end of the  $(D_n)$  diagram from the free module collapse into a single module, giving the

quiver

with  $4m$  vertices. Again,  $\tau$  is reflection across the horizontal axis.

**12.35.** We saw above the the quiver for the one-dimensional  $(E_6)$  singularity has the form

with 7 vertices and  $\tau$  given by reflection across the horizontal axis.

**12.36.** For the  $(E_7)$  singularity, every non-free indecomposable splits, giving 15 vertices in the AR quiver for the one-dimensional singularity.

The translate is reflection across the horizontal axis for every vertex except  $a$  and  $b$ , which are interchanged by  $\tau$ .

**12.37.** For the  $(E_8)$  singularity, once again every non-free indecomposable splits when flatted.

Here there are 17 vertices; the translate is reflection across the horizontal axis and interchanges  $a$  and  $b$ .

**12.38 Example.** Let  $A = k[[t^3, t^4, t^5]]$ . Then  $A$  is a finite birational extension of the  $(E_6)$  singularity  $R = k[[x, y]]/(x^3 + y^4) \cong k[[t^3, t^4]]$ , so has finite CM type by Theorem 4.13. In fact,  $A$  is isomorphic to the endomorphism ring of the maximal ideal of  $R$ . By Lemma 4.9 every indecomposable MCM  $R$ -module other than  $R$  itself is actually a MCM  $A$ -module, and  $\text{Hom}_R(M, N) = \text{Hom}_A(M, N)$  for all non-free MCM  $R$ -modules  $M$  and  $N$ . Thus the AR quiver for  $A$  is obtained from the one for  $R$  by erasing  $[R]$  and all the arrows into and out of  $[R]$ . As  $R$ -modules,  $A \cong (t^4, t^6)$ , so the quiver is the one below.

## §4 Exercises

**12.39 Exercise.** Prove that a short exact sequence  $0 \rightarrow N \rightarrow E \rightarrow M \rightarrow 0$  is split if and only if every homomorphism  $X \rightarrow M$  factors through  $E$ .

**12.40 Exercise.** Let  $R = D/(t^n)$ , where  $(D, t)$  is a complete DVR. Then the indecomposable finitely generated  $R$ -modules are  $D/(t), D/(t^2), \dots, D/(t^n) = R$ . Compute the AR sequences for each of the indecomposables, directly from the definition. (Hint: start with  $n = 2$ .)

**12.41 Exercise.** Prove, by mimicking the proof of Proposition 12.2, that (12.1.1) is an AR sequence ending in  $M$  if and only if it is an AR sequence starting from  $N$ . (Hint: Given  $\psi: N \rightarrow Y$ , it suffices to show that the short exact sequence obtained from the pushout is split. If not, use the lifting property to obtain an endomorphism  $\alpha$  of  $N$  such that either  $\alpha$  is an isomorphism and splits  $\psi$ , or  $\alpha - 1_N$  is an isomorphism and splits (12.1.1).)

**12.42 Exercise.** Assume that  $0 \rightarrow N \xrightarrow{i} E \xrightarrow{p} M \rightarrow 0$  is a non-split short exact sequence of MCM modules satisfying the lifting property to be an AR sequence ending in  $M$ . Prove that  $M$  is indecomposable.

**12.43 Exercise.** Prove Remark 12.5: there is an exact sequence

$$M^* \otimes_A N \xrightarrow{\rho} \text{Hom}_A(M, N) \rightarrow \underline{\text{Hom}}_A(M, N) \rightarrow 0,$$

where  $\rho$  sends  $f \otimes y$  to the homomorphism  $x \mapsto f(x)y$ .

**12.44 Exercise.** Let  $R$  be an hypersurface and  $M, N$  two MCM  $R$ -modules. Prove that  $\text{Ext}_R^{2i}(M, N) \cong \underline{\text{Hom}}_R(M, N)$  for all  $i \geq 1$ .

**12.45 Exercise** (Lemme d'Acyclicité, [PS73]). Let  $(A, \mathfrak{m})$  be a local ring and  $M_\bullet: 0 \rightarrow M_s \rightarrow \dots \rightarrow M_0 \rightarrow 0$  a complex of finitely generated  $A$ -modules. Assume that  $\text{depth } M_i \geq i$  for each  $i$ , and that every homology module  $H_i(M_\bullet)$  either has finite length or is zero. Then  $M_\bullet$  is exact.

**12.46 Exercise.** Prove that the natural map  $\rho_M^N: M^* \otimes_A N$  to  $\text{Hom}_A(M, N)$ , defined by  $\rho(f \otimes y)(x) = f(x)y$ , is an isomorphism if either  $M$  or  $N$  is projective. In particular  $\rho_M^M$  is an isomorphism if and only if  $M$  is projective.

**12.47 Exercise.** This exercise shows that if  $R$  is an Artinian local ring and  $M$  is an indecomposable  $R$ -module with an AR sequence

$$0 \longrightarrow N \longrightarrow E \longrightarrow M \longrightarrow 0,$$

then  $N \cong (\text{Tr } M)^\vee$ .

- (a) Let  $P_1 \longrightarrow P_0 \longrightarrow X \longrightarrow 0$  be an exact sequence with  $P_0, P_1$  finitely generated projective, and let  $Z$  be an arbitrary finitely generated  $R$ -module. Use the proof of Proposition 12.13 to show the existence of an exact sequence

$$0 \longrightarrow \text{Hom}_R(X, Z) \longrightarrow \text{Hom}_R(P_0, Z) \longrightarrow \text{Hom}_R(P_1, Z) \longrightarrow \text{Tr } X \otimes_R Z \longrightarrow 0$$

and conclude that we have an equality of lengths

$$\ell(\text{Hom}_R(X, Z)) - \ell(\text{Hom}_R(Z, (\text{Tr } X)^\vee)) = \ell(\text{Hom}_R(P_0, Z)) - \ell(\text{Hom}_R(P_1, Z)).$$

- (b) Let  $\sigma: 0 \longrightarrow A \xrightarrow{f} B \xrightarrow{g} C \longrightarrow 0$  be an exact sequence of finitely generated  $R$ -modules, and define the *defects* of  $\sigma$  on an  $R$ -module  $X$  by

$$\sigma_*(X) = \text{cok}[\text{Hom}_R(B, X) \longrightarrow \text{Hom}_R(A, X)]$$

$$\sigma^*(X) = \text{cok}[\text{Hom}_R(X, B) \longrightarrow \text{Hom}_R(X, C)].$$

Show that  $\ell(\sigma^*(X)) = \ell(\sigma_*((\text{Tr } X)^\vee))$  for every  $X$ . Conclude that the following two conditions are equivalent:

- (i) every homomorphism  $X \rightarrow C$  factors through  $g$ ;
- (ii) every homomorphism  $A \rightarrow (\text{Tr } X)^\vee$  factors through  $f$ .
- (c) Prove that if  $0 \rightarrow N \rightarrow E \rightarrow M \rightarrow 0$  is an AR sequence for  $M$ , then  $N \cong (\text{Tr } M)^\vee$ . (Hint: let  $h: N \rightarrow Y$  be given with  $Y$  indecomposable and not isomorphic to  $(\text{Tr } M)^\vee$ . Apply the previous part to  $X = \text{Tr}(Y^\vee)$ .)

**12.48 Exercise.** Prove that  $\text{rad}(M, N)/\text{rad}^2(M, N)$  is annihilated by the maximal ideal  $\mathfrak{m}$ , so is a finite-dimensional  $k$ -vector space. Your proof will actually show that the quotient is annihilated by the radical of  $\text{End}_R(M)$  (acting on the right) and the radical of  $\text{End}_R(N)$  (acting on the left).

**12.49 Exercise** ([Eis95, A.3.22]). If  $\sigma: A \rightarrow B \rightarrow C \rightarrow 0$  is an exact sequence, prove that (there exists a choice of  $\text{Tr } M$  such that) the sequence

$$0 \rightarrow \text{Hom}_R(\text{Tr } M, A) \rightarrow \text{Hom}_R(\text{Tr } M, B) \rightarrow \text{Hom}_R(\text{Tr } M, C) \rightarrow M \otimes_R A \rightarrow M \otimes_R B \rightarrow M \otimes_R C \rightarrow 0$$

is exact. In other words,  $\text{Tr}$  can be thought of as measuring the non-exactness of  $M \otimes_R -$  and, if we set  $N = \text{Tr } M$ , of  $\text{Hom}_R(N, -)$ .

**12.50 Exercise.** Say that an inclusion of modules  $A \subset B$  is *pure* if  $M \otimes_R A \rightarrow M \otimes_R B$  is injective for all  $R$ -modules  $M$ . If  $\sigma$  is as in the previous exercise with  $A \rightarrow B$  pure, then prove that

$$0 \rightarrow \text{Hom}_R(N, A) \rightarrow \text{Hom}_R(N, B) \rightarrow \text{Hom}_R(N, C) \rightarrow 0$$

is exact for every finitely presented module  $N$ . Conclude that if  $C$  is finitely presented, then  $\sigma$  splits. (See Exercise 7.23 for a different proof.)

## Countable Cohen-Macaulay type

We shift directions now, and focus on a representation type mentioned in passing in earlier chapters: countable type.

**13.1 Definition.** A Cohen-Macaulay local ring  $(R, \mathfrak{m})$  is said to have *countable Cohen-Macaulay type* if it admits only countably many isomorphism classes of maximal Cohen-Macaulay modules.

(By Theorem 2.2, it is equivalent to assume that there are only countably many *indecomposable* MCM modules, up to isomorphism.)

The property of countable type has received less attention than finite type, and correspondingly less is known about it. There is however an analogue of Auslander's Theorem (Theorem 13.3), as well as a complete classification (Theorem 13.16) of complete hypersurface singularities over an uncountable field with countable CM type, due to Buchweitz-Greuel-Schreyer [BGS87]. This has recently been revisited by Burban-Drozd [BD08, BD10]; we present here their approach, which echoes nicely the material in Chapter 4. They use a construction similar to the conductor square to prove that the  $(A_\infty)$  and  $(D_\infty)$  hypersurface singularities  $k[[x, y, z]]/(xy)$  and  $k[[x, y, z]]/(x^2y - z^2)$  have countable type. The material of Chapters 8 and 9 can then be used to show that, in any dimension, the higher-dimensional  $(A_\infty)$  and  $(D_\infty)$  singularities are the only hypersurfaces with countably infinite CM type. Apart from these results, there are a few examples due to Schreyer (see Section §4), but much remains to be done.

## §1 Structure

The main structural result on CM local rings of countable CM type was conjectured by Schreyer in 1987 [Sch87, Section 7]. He predicted that an analytic local ring  $R$  over the complex numbers having countable type has at most a one-dimensional singular locus, that is,  $R_{\mathfrak{p}}$  is regular for all  $\mathfrak{p} \in \text{Spec}(R)$  with  $\dim(R/\mathfrak{p}) > 1$ . In this section we prove Schreyer's conjecture more generally for all CM local rings satisfying a souped-up version of prime avoidance. In particular, this property holds if either the ring is complete or the residue field is uncountable. Some assumption of uncountability is necessary to avoid the degenerate case of a countable ring, which has only countably many isomorphism classes of finitely generated modules!

**13.2 Lemma** ([Bur72, Lemma 3]; see also [SV85]). *Let  $A$  be a Noetherian ring satisfying either of these conditions.*

- (i)  *$A$  is complete local, or*
- (ii) *there is an uncountable set of elements  $\{u_\lambda\}_{\lambda \in \Lambda}$  of  $A$  such that  $u_\lambda - u_\mu$  is a unit of  $A$  for every  $\lambda \neq \mu$ .*

*Let  $\{\mathfrak{p}_i\}_{i=1}^\infty$  be a countable set of prime ideals of  $R$ , and  $I$  an ideal with  $I \subseteq \bigcup_{i=1}^\infty \mathfrak{p}_i$ . Then  $I \subseteq \mathfrak{p}_i$  for some  $i$ .*

Notice that the second condition is satisfied if, for example,  $(A, \mathfrak{m})$  is local with  $A/\mathfrak{m}$  uncountable. In fact the proof will show that when (ii) is verified the ideals  $\mathfrak{p}_i$  need not even be prime.

We postpone the proof to the end of this section.

**13.3 Theorem.** *Let  $(R, \mathfrak{m})$  be an excellent CM local ring of countable CM type. Assume that  $R$  satisfies countable prime avoidance. Then the singular locus of  $R$  has dimension at most one.*

*Proof.* Set  $d = \dim R$ , and assume that the singular locus of  $R$  has dimension greater than one. Since  $R$  is excellent,  $\text{Sing} R$  is a closed subset of  $\text{Spec}(R)$ , defined by an ideal  $J$  such that  $\dim(R/J) \geq 2$ . Consider the set

$$\Omega = \left\{ \mathfrak{p} \in \text{Spec}(R) \setminus \{\mathfrak{m}\} \mid \mathfrak{p} = \text{Ann}_R \left( \text{Ext}_R^i(M, N) \right) \text{ for some MCM } M, N \right\}.$$

Then of course  $\Omega$  is a countable set, and each  $\mathfrak{p} \in \Omega$  contains  $J$ . Applying countable prime avoidance, we find an element  $r \in \mathfrak{m} \setminus \bigcup_{\mathfrak{p} \in \Omega} \mathfrak{p}$ . Choose a minimal prime  $\mathfrak{q}$  of  $J + (r)$ ; since  $\dim(R/J) \geq 2$  we have  $\mathfrak{q} \neq \mathfrak{m}$ , and  $\mathfrak{q} \notin \Omega$ .

Set  $M = \text{syz}_d^R(R/\mathfrak{q})$  and  $N = \text{syz}_{d+1}^R(R/\mathfrak{q})$ , and consider  $\mathfrak{a} = \text{Ann}_R(\text{Ext}_R^1(M, N))$ .

Clearly  $\mathfrak{q}$  is contained in  $\mathfrak{a}$ , as  $\text{Ext}_R^1(M, N) \cong \text{Ext}_R^d(R/\mathfrak{q}, N)$ . Since  $\mathfrak{q}$  contains  $J$ , the localization  $R_{\mathfrak{q}}$  is not regular, so the residue field  $R_{\mathfrak{q}}/\mathfrak{q}R_{\mathfrak{q}}$  has infinite projective dimension and  $\text{Ext}_R^1(M, N)_{\mathfrak{q}} \neq 0$ . Therefore  $\mathfrak{a} \subseteq \mathfrak{q}$ , and we see that  $\mathfrak{q} \in \Omega$ , a contradiction.  $\square$

**13.4 Remarks.** With a suitable assumption of prime avoidance for sets of cardinality  $\aleph_n$ , the same proof shows that if  $R$  has at most “ $\aleph_{m-1}$  CM type,” then the singular locus of  $R$  has dimension at most  $m$ .

Theorem 13.3 implies that for an excellent CM local ring of countable CM type, satisfying countable prime avoidance, there are at most finitely many non-maximal prime ideals  $\mathfrak{p}_1, \dots, \mathfrak{p}_n$  such that  $R_{\mathfrak{p}_i}$  is not a regular local ring. Each of these localizations has dimension  $d - 1$ . Naturally, one would like to know more about these  $R_{\mathfrak{p}_i}$ . Peeking ahead at the examples later on in this chapter, we find that in each of them, every  $R_{\mathfrak{p}_i}$  has finite

CM type! Whether or not this holds in general is still an open question. The next result gives partial information: at least each  $R_{\mathfrak{p}_i}$  has countable type. It is a nice application of MCM approximations (Chapter 11).

**13.5 Theorem.** *Let  $(R, \mathfrak{m})$  be a CM local ring with a canonical module. If  $R$  has countable CM type, then  $R_{\mathfrak{p}}$  has countable CM type for every  $\mathfrak{p} \in \text{Spec}(R)$ .*

*Proof.* Let  $\mathfrak{p} \in \text{Spec}(R)$  and suppose that  $\{M^\alpha\}$  is an uncountable family of finitely generated  $R$ -modules such that  $\{M_{\mathfrak{p}}^\alpha\}$  are non-isomorphic MCM  $R_{\mathfrak{p}}$ -modules. For each  $\alpha$  there is by Theorem 11.16 a MCM approximation of  $M^\alpha$

$$(13.5.1) \quad \chi^\alpha: \quad 0 \longrightarrow Y^\alpha \longrightarrow X^\alpha \longrightarrow M^\alpha \longrightarrow 0$$

with  $X^\alpha$  MCM and  $\text{injdim}_R Y^\alpha < \infty$ . Since there are only countably many non-isomorphic MCM modules, there are uncountably many short exact sequences

$$(13.5.2) \quad \chi^\beta: \quad 0 \longrightarrow Y^\beta \longrightarrow X \longrightarrow M^\beta \longrightarrow 0$$

where  $X$  is a fixed MCM module.

Localize at  $\mathfrak{p}$ ; since  $M_{\mathfrak{p}}^\beta$  is MCM over  $R_{\mathfrak{p}}$  and  $Y_{\mathfrak{p}}^\beta$  has finite injective dimension,  $\text{Ext}_R^1(M^\beta, Y^\beta)_{\mathfrak{p}} \cong \text{Ext}_{R_{\mathfrak{p}}}^1(M_{\mathfrak{p}}^\beta, Y_{\mathfrak{p}}^\beta) = 0$  by Prop. 11.3. In particular, the extension  $\chi^\beta$  splits when localized at  $\mathfrak{p}$ . This implies that  $M_{\mathfrak{p}}^\beta \mid X_{\mathfrak{p}}$  for uncountably many  $\beta$ , which cannot happen by Theorem 2.2.  $\square$

The results above, together with the examples in Section §4, suggest a plausible question:

**13.6 Question.** *Let  $R$  be a complete local Cohen-Macaulay ring of dimension at least one, and assume that  $R$  has an isolated singularity. If  $R$  has countable CM type, must it have finite CM type?*

Here is the proof we omitted earlier.

*Proof of Lemma 13.2.* Suppose first that  $(A, \mathfrak{m})$  is a complete local ring. Suppose that  $I \not\subseteq \mathfrak{p}_i$  for each  $i$ , but that  $I \subseteq \bigcup_i \mathfrak{p}_i$ . Obviously  $I \subseteq \mathfrak{m}$ . Since  $A$  is Noetherian, all chains in  $\text{Spec}(A)$  are finite, so we may replace each chain by its maximal element to assume that there are no inclusions among the  $\mathfrak{p}_i$ . Note that  $A$  is complete with respect to the  $I$ -adic topology [Mat89, Ex. 8.2].

Construct a Cauchy sequence in  $A$  as follows. Choose  $x_1 \in I \setminus \mathfrak{p}_1$ , and suppose inductively that we have chosen  $x_1, \dots, x_r$  to satisfy

(a)  $x_j \notin \mathfrak{p}_i$ , and

(b)  $x_i - x_j \in I^i \cap \mathfrak{p}_i$

for all  $i \leq j \leq r$ . If  $x_r \notin \mathfrak{p}_{r+1}$ , put  $x_{r+1} = x_r$ . Otherwise, take  $y_{r+1} \in (I^r \cap \mathfrak{p}_1 \cap \dots \cap \mathfrak{p}_r) \setminus \mathfrak{p}_{r+1}$  (this is possible since there are no containments among the  $\mathfrak{p}_i$ ) and set  $x_{r+1} = x_r + y_{r+1}$ . In either case, we have

(c)  $x_{r+1} \notin \mathfrak{p}_i$  for  $i \leq r+1$ , and

(d)  $x_{r+1} - x_r \in \mathfrak{m}^{r+1} \cap \mathfrak{p}_1 \cap \dots \cap \mathfrak{p}_r$ , so that if  $i < r+1$  then  $x_i - x_{r+1} \in \mathfrak{m}^i \cap \mathfrak{p}_i$ .

By condition (d),  $\{x_1, x_2, \dots\}$  is a Cauchy sequence, so converges to  $x \in A$ . Since  $x_i - x_s \in \mathfrak{p}_i$  for all  $i \leq s$ , and  $x_s \rightarrow x$ , we obtain  $x_i - x \in \mathfrak{p}_i$  for all  $i$ ,

since  $\mathfrak{p}_i$  is closed in the  $I$ -adic topology [Mat89, Thm. 8.14]. Therefore  $x \notin \mathfrak{p}_i$  for all  $i$ , but  $x \in I$ , a contradiction.

Now let  $\{u_\lambda\}_{\lambda \in \Lambda}$  be an uncountable family of elements of  $A$  as in (ii) of Lemma 13.2. Take generators  $a_1, \dots, a_k$  for the ideal  $I$ , and for each  $\lambda \in \Lambda$  set

$$z_\lambda = a_1 + u_\lambda a_2 + u_\lambda^2 a_3 + \cdots + u_\lambda^{k-1} a_k,$$

an element of  $I$ . Since  $\{\mathfrak{p}_i\}$  is countable, and  $I \subseteq \bigcup_i \mathfrak{p}_i$ , there exist some  $j \geq 1$  and uncountably many  $\lambda \in \Lambda$  such that  $z_\lambda \in \mathfrak{p}_j$ . In particular there are distinct elements  $\lambda_1, \dots, \lambda_k$  such that  $z_{\lambda_i} \in \mathfrak{p}_j$  for  $i = 1, \dots, k$ .

The  $k \times k$  Vandermonde matrix

$$P = \left( u_{\lambda_i}^{j-1} \right)_{i,j}$$

has determinant  $\prod_{i \neq j} (u_{\lambda_i} - u_{\lambda_j})$ , so is invertible. But

$$P \begin{pmatrix} a_1 & \cdots & a_k \end{pmatrix}^T = \begin{pmatrix} z_{\lambda_1} & \cdots & z_{\lambda_k} \end{pmatrix}^T,$$

so

$$\begin{pmatrix} a_1 & \cdots & a_k \end{pmatrix}^T = P^{-1} \begin{pmatrix} z_{\lambda_1} & \cdots & z_{\lambda_k} \end{pmatrix}^T,$$

which implies  $I = (a_1, \dots, a_k) \subseteq \mathfrak{p}_j$ . □

## §2 Burban-Drozd triples

Our goal in this section and the next is to classify the complete equicharacteristic hypersurfaces of countable CM type in characteristic other than 2. They are the “natural limits”  $(A_\infty)$  and  $(D_\infty)$  of the  $(A_n)$  and  $(D_n)$  singularities. This classification is originally due to Buchweitz, Greuel, and

Schreyer [BGS87]; they construct all the indecomposable MCM modules over the one-dimensional  $(A_\infty)$  and  $(D_\infty)$  hypersurface singularities, and use the property of countable simplicity (Definition 9.1) to show that no other one-dimensional hypersurfaces have countable type. They then use the double branched cover construction of Chapter 8 to obtain the result in all dimensions.

We modify this approach by describing a special case of some recent results of Burban and Drozd [BD10], which allow us to construct all the indecomposable MCM modules over the surface singularities rather than over the curves. In addition to its satisfying parallels with our treatment of hypersurfaces of finite CM type in Chapters 6 and 9, this method is also pleasantly akin to the “conductor square” construction in Chapter 4. It also allows us to write down, in a manner analogous to §4 of Chapter 9, a complete list of the indecomposable matrix factorizations over the two-dimensional  $(A_\infty)$  and  $(D_\infty)$  hypersurfaces.

**13.7 Notation.** Throughout this section we consider a reduced, CM, complete local ring  $(R, \mathfrak{m})$  of dimension 2 which is *not* normal. (The assumption that  $R$  is reduced is no imposition, thanks to Theorem 13.3.) We will impose further assumptions later on, cf. 13.12. Since normality is equivalent to both  $(R_1)$  and  $(S_2)$  by Proposition A.8, this means that  $R$  is not regular in codimension one. Let  $S$  be the integral closure of  $R$  in its total quotient ring. Since  $R$  is complete and reduced,  $S$  is a finitely generated  $R$ -module (Theorem 4.6), and is a direct product of complete local normal domains, each of which is CM.

Let  $\mathfrak{c} = (R :_R S) = \text{Hom}_R(S, R)$  be the conductor ideal as in Chapter 4,

the largest common ideal of  $R$  and  $S$ . Set  $\bar{R} = R/\mathfrak{c}$  and  $\bar{S} = S/\mathfrak{c}$ .

**13.8 Lemma.** *With notation as above we have the following properties.*

- (i) *The conductor ideal  $\mathfrak{c}$  is a MCM module over both  $R$  and  $S$ .*
- (ii) *The quotients  $\bar{R}$  and  $\bar{S}$  are (possibly non-reduced) one-dimensional CM rings with  $\bar{R} \subseteq \bar{S}$ .*
- (iii) *The diagram*

$$\begin{array}{ccc} R & \hookrightarrow & S \\ \downarrow & & \downarrow \\ \bar{R} & \hookrightarrow & \bar{S} \end{array}$$

*is a pullback diagram of ring homomorphisms.*

*Proof.* Since  $\mathfrak{c} = \text{Hom}_R(S, R)$ , Exercise 5.37 implies that  $\mathfrak{c}$  has depth 2 when considered as an  $R$ -module. Since  $R \subseteq S$  is a finite extension,  $\mathfrak{c}$  is also MCM over  $S$ .

The conductor  $\mathfrak{c}$  defines the non-normal locus of  $\text{Spec}R$ . Since for a height-one prime  $\mathfrak{p}$  of  $R$ ,  $R_{\mathfrak{p}}$  is normal if and only if it is regular, and  $R$  is not regular in codimension one, we see that  $\mathfrak{c}$  has height at most one in  $R$ . On the other hand,  $R$  is reduced, so its localizations at minimal primes are fields, and it follows that  $\mathfrak{c}$  has height exactly one in  $R$ . Thus  $\dim \bar{R} = 1$ , and, since  $\bar{R} \hookrightarrow \bar{S}$  is integral,  $\bar{S}$  is one-dimensional as well. Since  $\mathfrak{c}$  has depth 2, the quotients  $\bar{R}$  and  $\bar{S}$  have depth 1 by the Depth Lemma.

The third statement is easy to check. □

Recall from the exercises to Chapter 6 that the *reflexive product*  $N \cdot M = (N \otimes_R M)^{\vee\vee}$  of two  $R$ -modules  $M$  and  $N$  is a MCM  $R$ -module, where

$-^\vee = \text{Hom}_R(-, \omega_R)$ . In the special case  $N = S$ , the reflexive product  $S \cdot M$  inherits an  $S$ -module structure and so is a MCM  $S$ -module. Recall also that for any (not necessarily reflexive)  $S$ -module  $X$ , there is a short exact sequence (Exercise 13.32)

$$(13.8.1) \quad 0 \longrightarrow \text{tor}(X) \longrightarrow X \longrightarrow X^{\vee\vee} \longrightarrow L \longrightarrow 0,$$

where  $\text{tor}(X)$  denotes the torsion submodule of  $X$  and  $L$  is an  $S$ -module of finite length.

Let  $M$  be a MCM  $R$ -module. Set  $\overline{M} = M/cM$  and  $\overline{S \cdot M} = (S \cdot M)/c(S \cdot M)$ , modules over  $\overline{R}$  and  $\overline{S}$ , respectively. By Exercise 13.31, applied to  $\overline{R}$  and to  $R_{\mathfrak{p}}$ , respectively, we have  $\overline{M}^{\vee\vee} \cong \overline{M}/\text{tor}(\overline{M})$  and  $(S \cdot M)_{\mathfrak{p}} \cong (S_{\mathfrak{p}} \otimes_{R_{\mathfrak{p}}} M_{\mathfrak{p}})/\text{tor}(S_{\mathfrak{p}} \otimes_{R_{\mathfrak{p}}} M_{\mathfrak{p}})$ .

Finally, let  $A$  and  $B$  be the total quotient rings of  $\overline{R}$  and  $\overline{S}$ , respectively. We are thus faced with a commutative diagram of ring homomorphisms

$$(13.8.2) \quad \begin{array}{ccc} R & \hookrightarrow & S \\ \downarrow & & \downarrow \\ \overline{R} & \hookrightarrow & \overline{S} \\ \downarrow & & \downarrow \\ A & \hookrightarrow & B \end{array}$$

in which the top square is a pullback. Furthermore, the bottom row is an Artinian pair in the sense of Chapter 3, and a MCM  $R$ -module yields a module over the Artinian pair, as we now show.

**13.9 Lemma.** *Keep the notation established so far, and let  $M$  be a MCM  $R$ -module.*

- (i) *We have  $B = A \otimes_R S$ , that is, if  $U$  denotes the set of non-zero-divisors of  $\overline{R}$ , then  $B = U^{-1}\overline{S}$ . In particular  $B$  is a finitely generated  $A$ -module.*

(ii) *The natural homomorphism of  $B$ -modules*

$$\theta_M: B \otimes_A (A \otimes_{\overline{R}} \overline{M}) \xrightarrow{\cong} B \otimes_S (S \otimes_R M) \longrightarrow B \otimes_S (S \cdot M)$$

*is surjective.*

(iii) *The natural homomorphism of  $A$ -modules*

$$A \otimes_{\overline{R}} \overline{M} \longrightarrow B \otimes_A (A \otimes_{\overline{R}} \overline{M}) \xrightarrow{\theta_M} B \otimes_S (S \cdot M)$$

*is injective.*

*Proof.* For the first statement, set  $C = U^{-1}\overline{S}$ . Any  $b \in B$  can be written  $b = \frac{c}{v}$  where  $c \in C$  and  $v$  is a non-zerodivisor of  $S$ . Since  $C$  is Artinian, there is an integer  $n$  such that  $Cv^n = Cv^{n+1}$ , say  $v^n = dv^{n+1}$ . Then  $v^n(1 - dv) = 0$  so that  $dv = 1$  in  $B$ . This shows that  $b = dc \in C$ .

The exact sequence (13.8.1), with  $N = S \otimes_R M$ , shows that the cokernel of the natural homomorphism  $S \otimes_R M \longrightarrow S \cdot M$  has finite length. Hence that cokernel vanishes when we tensor with  $B$  and  $\theta_M$  is surjective.

To prove (iii), set  $N = (S \otimes_R M)/\text{tor}(S \otimes_R M)$ . Then the natural map  $M \longrightarrow N$  sending  $x \in M$  to  $\overline{1 \otimes x}$  is injective. It follows that the restriction  $\mathfrak{c}M \longrightarrow \mathfrak{c}N$  is also injective. In fact, it is also surjective: for any  $a \in \mathfrak{c}$ ,  $s \in S$ , and  $x \in M$ , we have

$$s(\overline{s \otimes x}) = \overline{as \otimes x} = \overline{1 \otimes asx}$$

in the image of  $\mathfrak{c}M$ , since  $as \in \mathfrak{c}$ .

Since  $N$  is torsion-free, we have an exact sequence

$$0 \longrightarrow N \longrightarrow N^{\vee\vee} \longrightarrow L \longrightarrow 0$$

where the duals  $(-)^{\vee}$  are computed over  $S$  and  $L$  is an  $S$ -module of finite length. It follows that the cokernel of the restriction  $\mathfrak{c}N \hookrightarrow \mathfrak{c}N^{\vee\vee}$  also has finite length. Consider the composition  $g: M \rightarrow N \rightarrow N^{\vee\vee}$  and the induced diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathfrak{c}M & \longrightarrow & M & \longrightarrow & \overline{M} & \longrightarrow & 0 \\ & & \downarrow f & & \downarrow g & & \downarrow h & & \\ 0 & \longrightarrow & \mathfrak{c}N^{\vee\vee} & \longrightarrow & N^{\vee\vee} & \longrightarrow & \overline{N^{\vee\vee}} & \longrightarrow & 0 \end{array}$$

with exact rows, where  $f$  is the restriction of  $g$  to  $\mathfrak{c}M$ . Since  $g$  is injective and the cokernel of  $f$  has finite length, the Snake Lemma implies that  $\ker h$  has finite length as well. Thus  $A \otimes_{\overline{R}} h: A \otimes_{\overline{R}} \overline{M} \rightarrow A \otimes_{\overline{R}} \overline{N^{\vee\vee}}$  is injective. Finally we observe that  $A \otimes_{\overline{R}} h$  is the natural homomorphism in (iii), since  $(S \cdot M)_{\mathfrak{p}} \cong (S_{\mathfrak{p}} \otimes_{R_{\mathfrak{p}}} M_{\mathfrak{p}}) / \text{tor}(S_{\mathfrak{p}} \otimes_{R_{\mathfrak{p}}} M_{\mathfrak{p}})$  for all primes  $\mathfrak{p}$  minimal over  $\mathfrak{c}$ .  $\square$

**13.10 Definition.** Keeping all the notation introduced in this section so far, consider the following *category of Burban-Drozd triples*  $\text{BD}(R)$ . The objects of  $\text{BD}(R)$  are triples  $(N, V, \theta)$ , where

- $N$  is a MCM  $S$ -module,
- $V$  is a finitely generated  $A$ -module, and
- $\theta: B \otimes_A V \rightarrow B \otimes_S N$  is a surjective homomorphism of  $B$ -modules such that the composition

$$V \rightarrow B \otimes_A V \xrightarrow{\theta} B \otimes_S N$$

is injective.

The induced map of  $A$ -modules  $V \rightarrow B \otimes_S N$  is called a *gluing map*.

A morphism between two triples  $(N, V, \theta)$  and  $(N', V', \theta')$  is a pair  $(f, F)$  such that  $f: V \rightarrow V'$  is a homomorphism of  $A$ -modules and  $F: N \rightarrow N'$  is a homomorphism of  $S$ -modules combining to make the diagram

$$\begin{array}{ccc} B \otimes_A V & \xrightarrow{\theta} & B \otimes_S N \\ 1 \otimes f \downarrow & & \downarrow 1 \otimes F \\ B \otimes_A V' & \xrightarrow{\theta'} & B \otimes_S N' \end{array}$$

commutative.

The category of Burban-Drozd triples is finer than the category of modules over the Artinian pair  $A \hookrightarrow B$ , since the homomorphism  $F$  above must be defined over  $S$  rather than just over  $B$ . In particular, an isomorphism of pairs  $(f, F): (V, N) \rightarrow (V', N')$  includes as part of its data an isomorphism of  $S$ -modules  $F: N \rightarrow N'$ , of which there are fewer than there are isomorphisms of  $B$ -modules  $B \otimes_S N \rightarrow B \otimes_S N'$ .

**13.11 Theorem** (Burban-Drozd). *Let  $R$  be a reduced CM complete local ring of dimension 2 which is not an isolated singularity. Let  $\mathbb{F}$  be the functor from MCM  $R$ -modules to  $\text{BD}(R)$  defined on objects by*

$$\mathbb{F}(M) = (S \cdot M, A \otimes_R M, \theta_M).$$

*Then  $\mathbb{F}$  is an equivalence of categories.*

Lemma 13.9 shows that the functor  $\mathbb{F}$  is well-defined. The proof that it is an equivalence is somewhat technical. For the applications we have in mind, a more restricted version suffices.

**13.12 Assumptions.** We continue to assume that  $R$  is a two-dimensional, reduced, CM, complete local ring and that  $S \neq R$  is its normalization. Let  $c$  be the conductor and  $\bar{R} = R/c$ ,  $\bar{S} = S/c$ . We impose two additional assumptions.

- (i) Assume that  $S$  is a *regular ring*. Since  $R$  is Henselian, this is equivalent to  $S$  being a direct product of regular local rings. Every MCM  $S$ -module is thus projective.
- (ii) Assume that  $\bar{R} = R/c$  is also a *regular local ring*, that is, a DVR. It follows that  $\bar{S}$  is a free  $\bar{R}$ -module, and even more, that a finitely generated  $\bar{S}$  module is MCM if and only if it is free over  $\bar{R}$ . Also, the total quotient ring  $A$  of  $\bar{R}$  is a field.

Under these simplifying assumptions, we define a category of modified Burban-Drozd triples  $\text{BD}'(R)$ .

**13.13 Definition.** Keep assumptions as in 13.12. A *modified Burban-Drozd triple*  $(N, X, \tilde{\theta})$  consists of the following data:

- $N$  is a finitely generated projective  $S$ -module;
- $X \cong \bar{R}^{(n)}$  is a free  $\bar{R}$  module of finite rank; and
- $\tilde{\theta}: X \rightarrow \bar{N} = N \otimes_S \bar{S}$  is a *split* injection of  $\bar{R}$ -modules such that in the induced commutative square

$$\begin{array}{ccc}
 A \otimes_{\bar{R}} X & \xrightarrow{A \otimes_{\bar{R}} \tilde{\theta}} & A \otimes_{\bar{R}} \bar{N} = (A \otimes_R S) \otimes_S \bar{N} \\
 \downarrow & & \parallel \\
 B \otimes_{\bar{R}} X & \longrightarrow & B \otimes_S \bar{N}
 \end{array}$$

the lower horizontal arrow is a split surjection. (The right-hand vertical arrow comes from Lemma 13.9(i).)

A morphism between modified triples  $(N, X, \tilde{\theta})$  and  $(N', X', \tilde{\theta}')$  is a pair  $(f, F)$  such that  $f: X \rightarrow X'$  is a homomorphism between free  $\overline{R}$ -modules and  $F: N \rightarrow N'$  is a homomorphism of  $S$ -modules fitting into a commutative diagram

$$\begin{array}{ccc} B \otimes_{\overline{R}} X & \longrightarrow & B \otimes_S N \\ 1 \otimes f \downarrow & & \downarrow 1 \otimes F \\ B \otimes_{\overline{R}} X' & \longrightarrow & B \otimes_S N' \end{array}$$

where the horizontal arrows are induced by  $\tilde{\theta}$  and  $\tilde{\theta}'$ , respectively.

Note that if  $(N, X, \tilde{\theta})$  is a modified Burban-Drozd triple, then  $(N, A \otimes_{\overline{R}} X, B \otimes_{\overline{R}} \tilde{\theta})$  is a Burban-Drozd triple.

**13.14 Lemma.** *Assume the hypotheses of 13.12, and let  $M$  be a MCM  $R$ -module. Then*

$$\mathcal{F}(M) = (S \cdot M, \overline{M}^{\vee\vee}, \tilde{\theta}_M)$$

*is a modified Burban-Drozd triple, where  $\tilde{\theta}_M: \overline{M}^{\vee\vee} \rightarrow \overline{S \cdot M}$  is the natural map.*

*Proof.* Since  $S$  is a regular ring of dimension 2, the reflexive  $S$ -module  $S \cdot M$  is in fact projective. Furthermore, the natural homomorphism of  $R$ -modules  $M \rightarrow S \cdot M$  is obtained by applying  $\text{Hom}_R(-, M)$  to the short exact sequence  $0 \rightarrow \mathfrak{c} \rightarrow R \rightarrow \overline{R} \rightarrow 0$ . In particular, we have the short exact sequence

$$(13.14.1) \quad 0 \rightarrow M \rightarrow S \cdot M \rightarrow E \rightarrow 0,$$

where  $E = \text{Ext}_R^1(\overline{R}, M)$ . Since  $E$  is annihilated by  $\mathfrak{c}$ , it is naturally a  $\overline{R}$ -module, and has depth one over  $R$  by the Depth Lemma applied to es(13.14.1). Since  $\overline{R}$  is a DVR by assumption, this implies that  $E$  is a free  $\overline{R}$ -module. The induced exact sequence of  $\overline{R}$ -modules

$$\overline{M} \longrightarrow \overline{S \cdot M} \longrightarrow E \longrightarrow 0,$$

where overlines indicate passage modulo  $\mathfrak{c}$ , is thus split exact on the right.

The projective  $\overline{S}$ -module  $\overline{S \cdot M}$  is torsion-free over  $\overline{R}$ , so there is a commutative diagram

$$\begin{array}{ccc} \overline{M} & \xrightarrow{\quad} & \overline{S \cdot M} \\ & \searrow & \nearrow \tilde{\theta}_M \\ & (\overline{M})^{\vee\vee} & \end{array}$$

where as usual  $-\vee$  is the canonical dual over  $R$ . Since  $\overline{M}^{\vee\vee} = \overline{M}/\text{tor}(\overline{M})$  by Exercise 13.32, we have  $A \otimes_{\overline{R}} \overline{M} = A \otimes_{\overline{R}} (\overline{M})^{\vee\vee}$ , so that

$$A \otimes_{\overline{R}} \tilde{\theta}_M : A \otimes_{\overline{R}} \overline{M}^{\vee\vee} \longrightarrow A \otimes_{\overline{R}} \overline{S \cdot M} = B \otimes_{\overline{S}} \overline{S \cdot M}$$

is injective by Lemma 13.9(iii). This shows that the kernel of  $\tilde{\theta}_M$  is torsion, hence zero as  $\overline{M}^{\vee\vee}$  is torsion-free. We therefore have the split-exact sequence of  $\overline{R}$ -modules

$$0 \longrightarrow \overline{M}^{\vee\vee} \xrightarrow{\tilde{\theta}_M} \overline{S \cdot M} \longrightarrow E \longrightarrow 0.$$

In the induced commutative diagram

$$\begin{array}{ccc} A \otimes_{\overline{R}} \overline{M}^{\vee\vee} & \xrightarrow{A \otimes_{\overline{R}} \tilde{\theta}_M} & A \otimes_{\overline{R}} \overline{S \cdot M} = B \otimes_{\overline{S}} N \\ & \searrow & \nearrow \\ & B \otimes_{\overline{R}} \overline{M}^{\vee\vee} & \end{array}$$

the northeasterly arrow is surjective by Lemma 13.9(ii), and is even split surjective since  $B \otimes_S N$  is projective over  $B$ . □

We now define a functor  $\mathcal{G}$  from  $\text{BD}'(R)$  to MCM  $R$ -modules which is inverse to  $\mathcal{F}$  on objects, still under the assumptions 13.12. Let  $(N, X, \tilde{\theta})$  be an object of  $\text{BD}'(R)$ . Let  $\pi: N \rightarrow \overline{N} = N/cN$  be the natural projection, and define  $M$  by the pullback diagram

$$(13.14.2) \quad \begin{array}{ccc} M & \longrightarrow & N \\ \downarrow & & \downarrow \pi \\ X & \xrightarrow{\tilde{\theta}} & \overline{N} \end{array}$$

of  $R$ -modules. Since  $\tilde{\theta}$  is a split injection of torsion-free modules over the DVR  $\overline{R}$ , its cokernel is an  $R$ -module of depth 1. This cokernel is isomorphic to the cokernel of  $M \rightarrow N$ , and it follows that  $\text{depth}_R M = 2$ , so that  $M$  is a MCM  $R$ -module. Define

$$\mathcal{G}(N, X, \tilde{\theta}) = M.$$

**13.15 Theorem.** *The functors  $\mathcal{F}$  and  $\mathcal{G}$  are inverses on objects, namely, for a MCM  $R$ -module  $M$  and a modified Burban-Drozd triple  $(N, X, \tilde{\theta})$ , we have*

$$\mathcal{G}\mathcal{F}(M) \cong M$$

and

$$\mathcal{F}\mathcal{G}(N, X, \tilde{\theta}) \cong (N, X, \tilde{\theta}).$$

*Proof.* For the first assertion, it suffices to show that

$$\begin{array}{ccc} M & \longrightarrow & S \cdot M \\ \downarrow & & \downarrow \pi \\ (\overline{M})^{\vee\vee} & \xrightarrow{\tilde{\theta}} & \overline{S \cdot M} \end{array}$$

is a pullback diagram. We have already seen that the homomorphisms  $M \rightarrow S \cdot M$  and  $(\overline{M})^{\vee\vee} \rightarrow \overline{S \cdot M}$  have the same cokernel, namely  $\text{Ext}_R^1(\overline{R}, M)$ .

It follows from the Snake Lemma that

$$\ker(M \rightarrow (\overline{M})^{\vee\vee}) \cong \ker(S \cdot M \rightarrow \overline{S \cdot M}).$$

From this it follows easily that  $M$  is the pullback of the diagram above.

For the converse, let  $(N, X, \tilde{\theta})$  be an object of  $\text{BD}'(R)$  and let  $M$  be defined by the pullback (13.14.2). Then  $\text{cok}(M \rightarrow N)$  is isomorphic to  $\text{cok}(\tilde{\theta}: X \rightarrow \overline{N})$ , and is in particular an  $\overline{R}$ -module. The Snake Lemma applied to the diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & cM & \longrightarrow & M & \longrightarrow & \overline{M} & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & cN & \longrightarrow & N & \longrightarrow & \overline{N} & \longrightarrow & 0 \end{array}$$

gives an exact sequence

$$0 \rightarrow \ker(\overline{M} \rightarrow \overline{N}) \rightarrow \text{cok}(cM \rightarrow cN) \rightarrow \text{cok}(M \rightarrow N).$$

This shows that  $\text{cok}(cM \rightarrow cN)$  is annihilated by  $c^2$ , so in particular is a torsion  $R$ -module. Now the commutative diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & cM & \longrightarrow & M & \longrightarrow & \overline{M} & \longrightarrow & 0 \\ & & \downarrow & & \parallel & & \downarrow & & \\ 0 & \longrightarrow & cN & \longrightarrow & M & \longrightarrow & X & \longrightarrow & 0 \end{array}$$

implies that  $\overline{M} \rightarrow X$  is surjective with torsion kernel. Therefore  $X \cong \overline{M}/\text{tor}(\overline{M}) \cong (\overline{M})^{\vee\vee}$ .

The inclusion  $M \hookrightarrow N$  induces a homomorphism  $S \cdot M \rightarrow N$  of reflexive  $S$ -modules, so in particular of reflexive  $R$ -modules. It suffices by Exercise 13.40 to prove that this is an isomorphism in codimension 1 in  $R$ , that

is,  $(S \cdot M)_p \rightarrow N_p$  is an isomorphism for all height-one primes  $p \in \text{Spec} R$ .

Over  $R_p$ , the localization of (13.14.2) is still a pullback diagram.

$$\begin{array}{ccccc} M_p & \longrightarrow & (S \cdot M)_p & \longrightarrow & N_p \\ \downarrow & & & & \downarrow \\ (\overline{M})_p & \longrightarrow & & \longrightarrow & \overline{N}_p \end{array}$$

Since  $(S \cdot M)_p \cong (S_p \otimes_{R_p} M_p) / \text{tor}(S_p \otimes_{R_p} M_p)$  and the bottom line is a module over the Artinian pair  $A \hookrightarrow B$ , we can use the machinery of Chapter 4 to see that  $(S \cdot M)_p \cong N_p$ .  $\square$

### §3 Hypersurfaces of countable CM type

We now apply Theorem 13.15 to obtain the complete classification of indecomposable MCM modules over the two-dimensional  $(A_\infty)$  and  $(D_\infty)$  complete hypersurface singularities, and show in particular that  $(A_\infty)$  and  $(D_\infty)$  have countably infinite CM type in all dimensions. Then we will establish the following result of Buchweitz-Greuel-Schreyer-Knörrer:

**13.16 Theorem** (Buchweitz-Greuel-Schreyer). *Let  $k$  be an algebraically closed field of characteristic different from 2, and let  $R = k[[x, y, x_2, \dots, x_d]]/(f)$ , where  $0 \neq f \in (x, y, x_2, \dots, x_d)^2$ . These are equivalent:*

- (i)  $R$  has countably infinite CM type;
- (ii)  $R$  is a countably simple singularity which is not simple, i.e. there are a countably infinite number of ideals  $L$  of  $k[[x, y, x_2, \dots, x_d]]$  such that  $f \in L^2$ ; and

(iii)  $R \cong k[[x, y, x_2, \dots, x_d]]/(g + x_2^2 + \dots + x_d^2)$ , where  $g \in k[x, y]$  is one of the following:

$$(A_\infty) \quad g = x^2; \text{ or}$$

$$(D_\infty) \quad g = x^2y.$$

Observe that the equations defining the  $(A_\infty)$  and  $(D_\infty)$  hypersurface singularities are natural limiting cases of the  $(A_n)$  and  $(D_n)$  equations as  $n \rightarrow \infty$ , since high powers of the variables are small in the  $m$ -adic topology. As we shall see, the same is true of the matrix factorizations over these singularities.

By Knörrer's Theorem 8.18, we may reduce the proof of the implication (iii)  $\implies$  (i) of Theorem 13.16 to the case of dimension  $d = 2$ . Thus we prove in Propositions 13.17 and 13.19 that the hypersurface singularities defined by  $x^2 + z^2$  and  $x^2y + z^2$ , respectively, have countably infinite CM type.

**13.17 Proposition.** *Let  $R = k[[x, y, z]]/(x^2 + z^2)$  be an  $(A_\infty)$  hypersurface singularity with  $k$  an algebraically closed field of characteristic other than 2. Let  $i \in k$  satisfy  $i^2 = -1$ . Let  $M$  be an indecomposable non-free MCM  $R$ -module. Then  $M$  is isomorphic to  $\text{cok}(zI - \varphi, zI + \varphi)$ , where  $\varphi$  is one of the following matrices over  $k[[x, y]]$ :*

- $\begin{pmatrix} ix \\ -ix \end{pmatrix}$  or  $\begin{pmatrix} -ix \\ ix \end{pmatrix}$ ; or
- $\begin{pmatrix} -ix & y^j \\ 0 & ix \end{pmatrix}$  for some  $j \geq 1$ .

In particular  $R$  has countable CM type.

*Proof.* For simplicity in the proof we replace  $x$  by  $ix$  to assume that

$$R = k[[x, y, z]]/(z^2 - x^2).$$

The integral closure  $S$  of  $R$  is then

$$S = R/(z - x) \times R/(z + x)$$

with the normalization homomorphism  $\nu: R \rightarrow S = S_1 \times S_2$  given by the diagonal embedding  $\nu(r) = (\bar{r}, \bar{r})$ . In particular,  $S$  is a regular ring.

Put another way,  $S$  is the  $R$ -submodule of the total quotient ring generated by the orthogonal idempotents

$$e_1 = \frac{z+x}{2z} \in S_1 \quad \text{and} \quad e_2 = \frac{z-x}{2z} \in S_2,$$

which are the identity elements of  $S_1$  and  $S_2$  respectively. In these terms,  $\nu(r) = r(e_1 + e_2)$  for  $r \in R$ .

The conductor of  $R$  in  $S$  is the ideal  $\mathfrak{c} = (x, z)R = (x, z)S$ , so that

$$\bar{R} = k[[x, y, z]]/(x, z) \cong k[[y]]$$

is a DVR, and  $\bar{S} \cong \bar{R} \times \bar{R}$  is a direct product of two copies of  $\bar{R}$ . The inclusion  $\bar{\nu}: \bar{R} \rightarrow \bar{S}$  is again diagonal,  $\bar{\nu}(\bar{r}) = (\bar{r}, \bar{r})$ . Finally, the quotient field  $A$  of  $\bar{R}$  is  $k((y))$ , which embeds diagonally into  $B = k((y)) \times k((y))$ . Thus all the assumptions of 13.12 are verified, and we may apply Theorem 13.15.

Let  $(N, X, \tilde{\theta})$  be an object of  $\text{BD}'(R)$ , so that  $N \cong S_1^{(p)} \oplus S_2^{(q)}$  for some  $p, q \geq 0$ , while  $X \cong \bar{R}^{(n)}$  for some  $n$  and  $\tilde{\theta}: X \rightarrow \bar{N}$  is a split injection. The gluing morphism  $\theta: B \otimes_{\bar{R}} X \rightarrow B \otimes_S N$  is thus a linear transformation

of  $A$ -vector spaces  $B^{(n)} \longrightarrow B^{(p)} \oplus B^{(q)}$ . More precisely,  $\tilde{\theta}$  defines a pair of matrices

$$(\theta_1, \theta_2) \in M_{p \times n}(A) \times M_{q \times n}(A)$$

representing an embedding

$$\theta = \begin{pmatrix} \theta_1 \\ \theta_2 \end{pmatrix} : A^{(n)} \longrightarrow B^{(p)} \oplus B^{(q)}$$

such that  $\theta$  is injective (has full column rank) and both  $\theta_1$  and  $\theta_2$  are surjective (full row rank). Thus in particular we have  $\max(p, q) \leq n \leq p + q$ .

Two pairs of matrices  $(\theta_1, \theta_2)$  and  $(\theta'_1, \theta'_2)$  define isomorphic modified Burban-Drozd triples if and only if there exist isomorphisms

$$\begin{aligned} f &: A^{(n)} \longrightarrow A^{(n)} \\ F_1 &: S_1^{(p)} \longrightarrow S_1^{(p)} \\ F_2 &: S_2^{(q)} \longrightarrow S_2^{(q)} \end{aligned}$$

such that as homomorphisms  $B^{(n)} \longrightarrow B^{(p)}$  and  $B^{(n)} \longrightarrow B^{(q)}$  we have

$$\begin{aligned} \theta'_1 &= F_1^{-1} \theta_1 f \\ \theta'_2 &= F_2^{-1} \theta_2 f. \end{aligned}$$

See Exercise 13.38 for a guided proof of the next lemma.

**13.18 Lemma.** *The indecomposable objects of  $BD'(R)$  are*

- (i)  $(S_1, \bar{R}, ((1), \emptyset))$  and  $(S_2, \bar{R}, (\emptyset, (1)))$
- (ii)  $(S_1 \times S_2, \bar{R}, ((1), (1)))$
- (iii)  $(S_1 \times S_2, \bar{R}, ((1), (y^j)))$  and  $(S_1 \times S_2, \bar{R}, ((y^j), (1)))$  for some  $j \geq 1$ .

Now we derive the matrix factorizations corresponding to the modified Burban-Drozd triples listed above. The pullback diagram corresponding to the triple  $(S_1, \bar{R}, ((1), \emptyset))$

$$\begin{array}{ccc} M & \longrightarrow & S_1 \\ \downarrow & & \downarrow \\ \bar{R} & \xrightarrow{\begin{pmatrix} 1 \\ \emptyset \end{pmatrix}} & \bar{S}_1 \end{array}$$

clearly gives  $M \cong S_1 = \text{cok}(z - x, z + x)$ , the first component of the normalization. Similarly, the modified triple  $(S_2, \bar{R}, (\emptyset, (1)))$  yields  $M \cong S_2 = \text{cok}(z + x, z - x)$ .

The diagonal map  $((1), (1)) : \bar{R} \rightarrow \bar{S}_1 \times \bar{S}_2$  obviously defines the free module  $R$ . By symmetry, it suffices now to consider the modified Burban-Drozd triple  $(S_1 \times S_2, \bar{R}, ((1), (y^j)))$ . The pullback diagram

$$\begin{array}{ccc} M & \longrightarrow & S_1 \times S_2 \\ \downarrow & & \downarrow \\ \bar{R} & \xrightarrow{\begin{pmatrix} 1 \\ y^j \end{pmatrix}} & \bar{S}_1 \times \bar{S}_2 \end{array}$$

defines  $M$  as the module of ordered triples of polynomials

$$(f(y), g_1(x, y, x), g_2(x, y, -x)) \in \bar{R} \times S_1 \times S_2$$

such that  $f - g_1 \in \mathfrak{c}S_1$  and  $y^j f - g_2 \in \mathfrak{c}S_2$ . This is equal to the  $R$ -submodule of  $S$  generated by  $\mathfrak{c} = (x, z) = (z + x, z - x)$  and  $e_1 + y^j e_2$ , where again  $e_1 = (z + x)/2z$  and  $e_2 = (z - x)/2z$  are idempotent. Multiplying by the non-zero-divisor

$(2z)^j = ((z-x) + (z+x))^j$  to knock the generators down into  $R$ , we find

$$\begin{aligned} (x, z, e_1 + y^j e_2)S &\cong (2z)^j \left( z+x, z-x, \frac{z+x}{2z} + y^j \frac{z-x}{2z} \right) \\ &= \left( (z+x)^{j+1}, (z-x)^{j+1}, (2z)^j \left( \frac{z+x}{2z} \right)^j + y^j (2z)^j \left( \frac{z-x}{2z} \right)^j \right) \\ &= \left( (z+x)^{j+1}, (z-x)^{j+1}, (z+x)^j + (z-x)^j y^j \right) \\ &= \left( (z-x)^j, (z+x)^j + (z-x)^j y^j \right). \end{aligned}$$

The matrix factorization

$$\left( \begin{pmatrix} z+x & y^j \\ 0 & z-x \end{pmatrix}, \begin{pmatrix} z-x & -y^j \\ 0 & z+x \end{pmatrix} \right)$$

provides a minimal free resolution of this ideal and finishes the proof.  $\square$

As an aside, we note that the restriction on the characteristic of  $k$  could be removed by working instead with the hypersurface defined by  $xz$  instead of  $x^2+z^2$ . In characteristic not two, of course the hypersurface singularities are isomorphic, and the former can be shown to have countable type in all characteristics.

**13.19 Proposition.** *Let  $R = k[[x, y, z]]/(x^2y+z^2)$  be a  $(D_\infty)$  hypersurface singularity, where  $k$  is a field of arbitrary characteristic. Let  $M$  be an indecomposable non-free MCM  $R$ -module. Then  $M$  is isomorphic to  $\text{cok}(zI - \varphi, zI + \varphi)$  for  $\varphi$  one of the following matrices over  $k[[x, y]]$ .*

- $\begin{pmatrix} 0 & -y \\ x^2 & 0 \end{pmatrix}$
- $\begin{pmatrix} 0 & -xy \\ x & 0 \end{pmatrix}$

$$\bullet \begin{pmatrix} & -xy & 0 \\ & -y^{j+1} & xy \\ x & 0 & \\ y^j & -x & \end{pmatrix} \text{ for some } j \geq 1$$

$$\bullet \begin{pmatrix} & -xy & 0 \\ & -y^{j+1} & x \\ x & 0 & \\ y^{j+1} & -xy & \end{pmatrix} \text{ for some } j \geq 1$$

In particular  $R$  has countable CM type.

*Proof.* In this case, the integral closure of  $R$  is obtained by adjoining the element  $t = \frac{z}{x}$  of the quotient field, so  $S = R\left[\frac{z}{x}\right]$ . The maximal ideal of  $R$  is then  $(x, y, z)R = (x, t^2, tx)R$  and that of  $S$  is  $(x, t)S$ . In particular,  $S$  is a regular local ring. The conductor is now  $\mathfrak{c} = (x, z)R = (x, tx)S = xS$ , so that  $\bar{R} = R/(x, z) \cong k[[t^2]]$  and  $S = S/(x) \cong k[[t]]$  are both DVRs, with  $\bar{v}: \bar{R} \rightarrow \bar{S}$  the obvious inclusion. The Artinian pair  $A = k((t^2)) \rightarrow B = k((t))$  is thus a field extension of degree 2.

Let  $(N, X, \tilde{\theta})$  be an object of  $\text{BD}'(R)$ . The normalization  $S$  being regular local,  $N \cong S^{(n)}$  is a free  $S$ -module, while  $X \cong \bar{R}^{(m)}$  is a free  $\bar{R}$ -module. The gluing map  $\theta: B \otimes_A V \cong B^{(m)} \rightarrow B^{(n)} \cong B \otimes_S N$  is thus simply an  $n \times m$  matrix over  $B$  with full row rank. The condition that the composition  $A^{(m)} \rightarrow B^{(n)}$  be injective amounts to writing  $\theta = \theta_0 + t\theta_1$  and requiring  $\begin{pmatrix} \theta_0 \\ \theta_1 \end{pmatrix}: A^{(m)} \rightarrow A^{(2n)} \cong B^{(n)}$  to have full column rank as a matrix over  $A$ . In particular we have  $n \leq m \leq 2n$ .

Two  $n \times m$  matrices  $\theta, \theta'$  over  $B$  define isomorphic modified Burban-Drozd triples if and only if there exist isomorphisms

$$f: A^{(m)} \longrightarrow A^{(m)} \quad \text{and} \quad F: S^{(n)} \longrightarrow S^{(n)}$$

such that, when considered as matrices over  $B$ , we have

$$\theta' = F^{-1}\theta f.$$

In other words, we are allowed to perform row operations over  $\bar{S} = k[[t]]$  and column operations over  $A = k((t^2))$ .

**13.20 Lemma.** *The indecomposable objects of  $\text{BD}'(R)$  are*

- (i)  $(S, \bar{R}, (1))$
- (ii)  $(S, \bar{R}, (t))$
- (iii)  $(S, \bar{R}^{(2)}, (1 \ t))$
- (iv)  $(S^{(2)}, \bar{R}^{(2)}, \begin{pmatrix} 1 & t \\ t^m & 0 \end{pmatrix})$  for some  $d \geq 1$ .

We leave the proof of Lemma 13.20 as Exercise 13.39.

The MCM  $R$ -module corresponding to  $(S, \bar{R}, (1))$  is given by the pullback

$$\begin{array}{ccc} M & \longrightarrow & S \\ \downarrow & & \downarrow \\ \bar{R} & \longrightarrow & \bar{S} \end{array}$$

where the bottom line is the given inclusion of  $A = k((t^2))$  into  $B = k((t))$ , so is clearly the free module  $R$ . In  $(S, \bar{R}, (t))$ , the natural inclusion is replaced by multiplication by  $t$ . The pullback  $M$  is the  $R$ -submodule of  $S$  generated

by  $c = (x, z)$  and  $t = \frac{z}{x}$ . Multiplying through by the non-zero-divisor  $x$ , we find

$$\begin{aligned} M &\cong (x^2, xz, z)R \\ &= (x^2, z)R \\ &\cong \text{cok} \left( \begin{pmatrix} z & y \\ -x^2 & z \end{pmatrix}, \begin{pmatrix} z & -y \\ x^2 & z \end{pmatrix} \right). \end{aligned}$$

The modified Burban-Drozd triple  $(S, \overline{R}, (1 \ t))$  is defined by the isomorphism  $\theta: A \xrightarrow{(1 \ t)} B$ , so corresponds to the normalization  $S$ , which has matrix factorization

$$\left( \begin{pmatrix} z & xy \\ -x & z \end{pmatrix}, \begin{pmatrix} z & -xy \\ x & z \end{pmatrix} \right).$$

Finally, let  $M$  be the  $R$ -module defined by the pullback

$$\begin{array}{ccc} M & \longrightarrow & S^2 \\ \downarrow & & \downarrow \\ \overline{R}^{(2)} & \xrightarrow{\begin{pmatrix} 1 & t \\ t^m & 0 \end{pmatrix}} & \overline{S}^{(2)}. \end{array}$$

Then  $M$  is the  $R$ -submodule of  $S^{(2)}$  generated by  $cS^{(2)}$  and the elements

$$\begin{pmatrix} 1 \\ t^m \end{pmatrix}, \begin{pmatrix} t \\ 0 \end{pmatrix}.$$

Substitute  $t = \frac{z}{x}$  to see that the generators are therefore

$$\begin{pmatrix} x \\ 0 \end{pmatrix}, \begin{pmatrix} z \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ x \end{pmatrix}, \begin{pmatrix} 0 \\ z \end{pmatrix}, \begin{pmatrix} 1 \\ z^m/x^m \end{pmatrix}, \text{ and } \begin{pmatrix} z/x \\ 0 \end{pmatrix}.$$

Notice that the second generator is a multiple of the last. Multiplication by  $x$  on the first component and  $x^m$  on the second is injective on  $S^2$ , so  $M_1$  is isomorphic to the module generated by

$$\begin{pmatrix} x^2 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ x^{m+1} \end{pmatrix}, \begin{pmatrix} 0 \\ x^m z \end{pmatrix}, \begin{pmatrix} x \\ z^m \end{pmatrix}, \quad \text{and} \quad \begin{pmatrix} z \\ 0 \end{pmatrix}.$$

Observe that

$$\begin{pmatrix} x^2 \\ 0 \end{pmatrix} = x \begin{pmatrix} x \\ z^m \end{pmatrix} - \begin{pmatrix} 0 \\ xz^m \end{pmatrix},$$

so we may replace the first generator by  $\begin{pmatrix} 0 \\ xz^m \end{pmatrix}$ , getting

$$M = \left\langle \begin{pmatrix} 0 \\ xz^m \end{pmatrix}, \begin{pmatrix} 0 \\ x^{m+1} \end{pmatrix}, \begin{pmatrix} 0 \\ x^m z \end{pmatrix}, \begin{pmatrix} x \\ z^m \end{pmatrix}, \begin{pmatrix} z \\ 0 \end{pmatrix} \right\rangle.$$

At this point we distinguish two cases. If  $m = 2j$  is even, then using the relation  $xy^2 = -z^2$  in  $R$ ,

$$xz^m = xz^{2j} = xx^{2j}y^j = x^{m+1}y^j$$

up to sign, so the first generator is a multiple of the second. If  $m = 2j + 1$  is odd, then

$$xz^m = xz^{2j+1} = xx^{2j}y^jz = x^{m+1}y^jz$$

again up to sign, so that again the first generator is a multiple of the second. In either case,  $M$  is generated by

$$\left\langle \begin{pmatrix} x \\ z^m \end{pmatrix}, \begin{pmatrix} 0 \\ x^m z \end{pmatrix}, \begin{pmatrix} z \\ 0 \end{pmatrix} \begin{pmatrix} 0 \\ x^{m+1} \end{pmatrix} \right\rangle.$$

Now it's easy to check that in the case where  $m = 2j + 1, j \geq 0$ , is odd,

$$M \cong \text{cok} \left( \begin{pmatrix} z & -xy & 0 \\ & z & -y^{j+1} & x \\ x & 0 & z & \\ y^{j+1} & -xy & & z \end{pmatrix}, \begin{pmatrix} z & xy & 0 \\ & z & y^{j+1} & -x \\ -x & 0 & z & \\ -y^{j+1} & xy & & z \end{pmatrix} \right)$$

and in case  $m = 2j, j \geq 0$ , is even,

$$M \cong \text{cok} \left( \begin{pmatrix} z & -xy & 0 \\ & z & -y^{j+1} & xy \\ x & 0 & z & \\ y^j & -xy & & z \end{pmatrix}, \begin{pmatrix} z & xy \\ & z & y^{j+1} & -xy \\ -x & 0 & z & \\ -y^j & xy & & z \end{pmatrix} \right)$$

(after a permutation of the generators). □

Together with Theorem 8.18, Propositions 13.17 and 13.19 show that the  $(A_\infty)$  and  $(D_\infty)$  hypersurface singularities have countable CM type in all dimensions. To show that these are the only ones and complete the proof of Theorem 13.16, we need the following classification of countably simple singularities (the proof of which is considerably simpler than the corresponding classification for simple singularities on pages 204–210).

**13.21 Theorem.** *Let  $k$  be an algebraically closed field of characteristic different from 2, and let  $R = k[[x, y]]/(f)$  be a one-dimensional complete hypersurface singularity over  $k$ . If  $R$  is a countably simply but not simple singularity, then either  $R \cong k[[x, y]]/(x^2)$  or  $R \cong k[[x, y]]/(x^2y)$ .*

*Proof.* By Lemma 9.3, we see that  $e(R) \leq 3$  and  $f \notin (\alpha, \beta^2)^3$  for every  $\alpha, \beta \in (x, y)$ . If in addition  $R$  is reduced, then by Remark 9.13 it is a simple

singularity. Hence we may assume that in the irreducible factorization  $f = uf_1^{e_1} \cdots f_r^{e_r}$ , with  $u$  a unit and the  $f_i$  distinct irreducibles, we have  $e_i \geq 2$  for at least one  $i$ . Say  $e_1 \geq 2$ . Since  $f$  is not divisible by any cube (by Lemma 9.3(iia)) we must have  $e_1 = 2$ . Since the multiplicity of  $R$  is at most 3, we must have  $r \leq 2$  and that each  $f_i$  has non-zero linear term. Make the linear change of variable sending  $\sqrt{u}f_1$  to  $x$ , so that now  $f = x^2f_2^{e_2}$  with  $e_2 = 0$  or 1. Now if  $e_2 = 0$  we have  $f = x^2$ , while if  $e_2 = 1$  we make the change of variables sending  $f_2$  to  $y$ , so that  $f = x^2y$ .  $\square$

Now we finish the proof of the main theorem.

*Proof of Theorem 13.16.* If  $R = k[[x, y, x_2, \dots, x_d]]/(f)$  has countably infinite CM type, then  $R$  is a countably simple singularity but not simple by Theorem 9.2.

To prove that countably simplicity implies one of the forms in item (iii), we may, as in the proof of Theorem 9.8, reduce to the case of dimension one, where Theorem 13.21 finishes.

Finally, Propositions 13.17 and 13.19 show that the  $(A_\infty)$  and  $(D_\infty)$  singularities have countably infinite CM type, completing the proof.  $\square$

We remarked above that the equations defining the  $(A_\infty)$  and  $(D_\infty)$  hypersurface singularities, and even the matrix factorizations over them, are “natural limits” of the cases  $(A_n)$  and  $(D_n)$ . This suggests the following question.

**13.22 Question.** *Are all CM local rings of countable CM type “natural limits” of a “series of singularities” of finite CM type? For those that are, are the*

*indecomposable MCM modules “limits” of MCM modules over singularities in the series?*

To address the question, of course, the first order of business must be to give meaning to the phrases in quotation marks. This is problematic, as Arnold remarked [Arn81]: “Although the series undoubtedly exist, it is not at all clear what a series of singularities is.”

## §4 Other examples

Besides the hypersurface examples of the last section, very few non-trivial examples of countable CM type are known. In this section we present a few, taken from Schreyer’s survey article [Sch87].

In dimension one, we have the following example, which will return triumphantly in Chapter 16.

**13.23 Example.** Consider the one-dimensional ( $D_\infty$ ) hypersurface singularity  $R = k[[x, y]]/(x^2y)$ , where  $k$  is a field of arbitrary characteristic. Set  $E = \text{End}_R(\mathfrak{m})$ , where  $\mathfrak{m} = (x, y)$  is the maximal ideal. Then we claim that

$$\begin{aligned} E &\cong k[[x, y, z]]/(yz, x^2 - xz, xz - z^2) \\ &\cong k[[a, b, c]]/(ab, ac, c^2). \end{aligned}$$

In particular  $E$  is local, so has countable CM type by Lemma 4.9.

That the two alleged presentations of  $E$  are isomorphic is a simple matter of a linear change of variables:

$$a = z, \quad b = y, \quad c = x - z.$$

To show that in fact  $E$  is isomorphic to  $A = k[[x, y, z]]/(yz, x^2 - xz, xz - z^2)$ , note that the element  $x + y$  of  $R$  is a non-zerodivisor, and that the fraction  $z := \frac{x^2}{x+y}$  is in  $\text{End}_R(\mathfrak{m})$  but not in  $R$ . Now  $E = \text{Hom}_R(\mathfrak{m}, R)$  since  $\mathfrak{m}$  does not have a free direct summand, and it follows by duality over the Gorenstein ring  $R$  that  $E/R \cong \text{Ext}_R^1(R/\mathfrak{m}, R) \cong k$ . Therefore  $E = R[z]$ . Since

$$z^2 = \frac{x^2(x+y)^2}{(x+y)^2} = x^2 \in \mathfrak{m},$$

$E$  is local. One verifies the relations  $yz = 0$  and  $x^2 = xz = z^2$  in  $E$ . Thus we have a surjective homomorphism of  $R$ -algebras  $A \rightarrow E$ . Since  $R$  is a subring of  $E$ , and the inclusion  $R \hookrightarrow E$  factors through  $A$ , we see that  $R$  is also a subring of  $A$ , and that the surjection  $A \rightarrow E$  fixes  $R$ .

The induced homomorphism  $A/R \rightarrow E/R$  is still surjective, and in fact is bijective since  $A/R$  is simple as well. It follows from the Five Lemma that  $A \rightarrow E$  is an isomorphism.

By Lemma 4.9, the indecomposable MCM  $E$ -modules are precisely the non-free indecomposable MCM  $R$ -modules. By Propositions 8.15 and 13.19, these are the cokernels of the following matrices over  $R = k[[x, y]]/(x^2y)$ :

$$(y); \quad (x^2); \quad (x); \quad (xy)$$

$$\begin{pmatrix} x \\ y^j & -x \end{pmatrix}; \quad \begin{pmatrix} xy \\ y^{j+1} & -xy \end{pmatrix}; \quad \begin{pmatrix} x \\ y^{j+1} & -xy \end{pmatrix}; \quad \begin{pmatrix} xy \\ y^{j+1} & -x \end{pmatrix}$$

for  $j \geq 1$ .

For two-dimensional examples, we note that Herzog's Proposition 6.2 implies the following.

**13.24 Proposition.** *Let  $S$  be a two-dimensional CM local ring which is Gorenstein in codimension one. (For example,  $S$  could be one of the two-dimensional  $(A_\infty)$  and  $(D_\infty)$  hypersurface singularities.) Let  $G$  be a finite group with order invertible in  $S$ , acting by linear changes of variables on  $S$ . Set  $R = S^G$ . If  $S$  has countable CM type, then  $R$  has countable CM type.*

**13.25 Example.** Let  $R$  be the two-dimensional  $(A_\infty)$  hypersurface  $R = k[[x, y, z]]/(xy)$ , where  $k$  is an algebraically closed field of characteristic not 2, and let the cyclic group  $\mathbb{Z}/r\mathbb{Z}$  act on  $R$ , the generator sending  $(x, y, z)$  to  $(x, \zeta_r y, \zeta_r z)$ , where  $\zeta_r$  is a primitive  $r^{\text{th}}$  root of unity. The invariant subring is generated by  $x, y^r, y^{r-1}z, \dots, z^r$  (see Exercise 5.35), and is thus isomorphic to the quotient of  $k[[t_0, t_1, \dots, t_r, x]]$  by the  $2 \times 2$  minors of

$$\begin{pmatrix} t_0 & \cdots & t_{r-1} & 0 \\ t_1 & \cdots & t_r & x \end{pmatrix}.$$

**13.26 Example.** Let  $R$  be the two-dimensional  $(D_\infty)$  hypersurface  $k[[x, y, z]]/(x^2y - z^2)$ , where  $k$  is an arbitrary field. Let  $r = 2m + 1$  be an odd positive integer, and let  $\mathbb{Z}/r\mathbb{Z}$  act on  $R$  by the action sending  $(x, y, z) \mapsto (\zeta_r^2 x, \zeta_r^{-1} y, \zeta_r^{m+2} z)$ .

The ring of invariants is complicated to describe in general; see Exercise 5.36. If  $m = 1$ , it is generated by  $x^3, xy^2, y^3, z$  and hence is isomorphic to

$$k[[a, b, c, z]]/I_2 \begin{pmatrix} a & z^2 & b \\ z^2 & b & c \end{pmatrix}.$$

If  $m = 2$ , there are 7 generating invariants

$$x^5, x^3y, x^3z, xy^2, xyz, y^5, y^4z,$$

and 15 relations among them. When  $m = 4$ , the greatest common divisor of  $m + 2$  and  $2m + 1$  is no longer 1, and things get really weird.

**13.27 Remark.** As Schreyer points out [Sch87], the phenomenon observed in Question 13.22 repeats here. The one-dimensional example  $E$  is obtained as a limit of the endomorphism rings of the maximal ideals of  $D_n$ :

$$\text{End}_{D_n}(\mathfrak{m}) \cong k[[x, y, z]] / I_n,$$

where  $I_n$  is the ideal of  $2 \times 2$  minors of  $\begin{pmatrix} y & x-z & 0 \\ x-z & y^n & z \end{pmatrix}$ .

Similarly, for example 13.25 we may take the quotient of  $k[[t_0, t_1, \dots, t_{r+1}]]$  by the  $2 \times 2$  minors of

$$\begin{pmatrix} t_0 & \cdots & t_{r-1} & t_r^n \\ t_1 & \cdots & t_r & t_{r+1} \end{pmatrix},$$

and for example 13.26 with  $m = 1$ , we take the quotient of  $k[[a, b, c, d]]$  by the  $(2 \times 2)$  minors of

$$\begin{pmatrix} d^2 + a^n & c & b \\ b & d^2 & a \end{pmatrix}.$$

As assured by Theorem 7.19, both of these are invariant rings of a finite group acting on power series, the first for a cyclic group action  $\mathcal{C}_{nr-n+1, n}$ , and the second by a binary dihedral  $\mathcal{D}_{2+3n, 2+2n}$  (cf. [Sch87, Rie81]).

These examples add some strength to Question 13.22. We also mention the related question, first asked by Schreyer [Sch87]:

**13.28 Question.** *Is every CM local ring of countable CM type a quotient of one of the  $(A_\infty)$  or  $(D_\infty)$  hypersurface singularities by a finite group action?*

Burban and Drozd have recently announced a negative answer to this question [BD10]. Namely, set

$$A_{m,n} = k[[x_1, x_2, y_1, y_2, z]] / (x_1 y_1, x_1 y_2, x_2 y_1, x_2 y_2, x_1 z - x_2^n, y_1 z - y_2^m).$$

Then  $A_{m,n}$  has countable CM type for every  $n, m \geq 0$ . For  $n = m$  this ring is isomorphic to a ring of invariants of the  $(A_\infty)$  hypersurface, but for  $m \neq n$  it is not.

## §5 Exercises

**13.29 Exercise.** Let  $R = \mathbb{Q}[x, y, z]_{(x,y,z)}/(x^2)$ . The completion  $\widehat{R} = \mathbb{Q}[[x, y, z]]/(x^2)$  has a two-dimensional singular locus and therefore has uncountable CM type. Show that only countably many indecomposable  $\widehat{R}$ -modules are used in direct-sum decompositions of modules of the form  $\widehat{R} \otimes_R M$ , for MCM  $R$ -modules  $M$ . Thus the set  $\mathcal{U}$  in the proof of Theorem 10.1 is properly contained in the set of all MCM  $\widehat{R}$ -modules.

**13.30 Exercise.** Let  $R$  be a commutative ring and  $M$  a finitely generated  $R$ -module. Set  $(-)^* = \text{Hom}_R(-, R)$ . Define  $\sigma_M: M \rightarrow M^{**}$  to be the natural biduality homomorphism, defined by  $\sigma_M(m)(f) = f(m)$ . Prove that the kernel of  $\sigma_M$  is the torsion submodule of  $M$ ,  $\text{tor}(M)$ . Prove the analogous statement for  $R$  CM local with canonical module  $\omega$  and  $\tau_M: M \rightarrow M^{\vee\vee}$ , where  $(-)^{\vee} = \text{Hom}_R(-, \omega)$ .

**13.31 Exercise.** Let  $R$  be a one-dimensional CM local ring with canonical module  $\omega$ , and let  $M$  be a finitely generated  $R$ -module. Prove that  $M^{\vee\vee} \cong M/\text{tor}(M)$ .

**13.32 Exercise.** Let  $R$  be a two-dimensional local ring which is Gorenstein on the punctured spectrum. Let  $M$  be a finitely generated  $R$ -module. Prove

that there is an exact sequence

$$0 \longrightarrow \operatorname{tor}(M) \longrightarrow M \xrightarrow{\sigma_M} M^{**} \longrightarrow L \longrightarrow 0,$$

where  $\sigma_M$  is the biduality homomorphism of Exercise 13.30 and  $L$  is a module of finite length. If  $R$  is CM with canonical module  $\omega$ , prove that there is also an exact sequence

$$0 \longrightarrow \operatorname{tor}(M) \longrightarrow M \xrightarrow{\tau_M} M^{\vee\vee} \longrightarrow L' \longrightarrow 0,$$

where  $\tau_M$  is also as in Exercise 13.30 and  $L'$  also has finite length.

**13.33 Exercise.** Let  $R$  be a reduced local ring satisfying  $(S_2)$  and let  $M$  and  $N$  be two finitely generated  $R$ -modules. Assume that  $N$  is reflexive. Prove that

$$\operatorname{Hom}_R(M, N) = \operatorname{Hom}_R(M^{**}, N).$$

If in addition  $R$  is CM with canonical module  $\omega$ , then

$$\operatorname{Hom}_R(M, N) = \operatorname{Hom}_R(M^{\vee\vee}, N).$$

(Hint: first reduce to the torsion-free case.)

**13.34 Exercise.** Let  $R$  be a reduced CM two-dimensional local ring with canonical module  $\omega$ . Assume that  $R$  is Gorenstein in codimension one. Prove that there is a natural isomorphism  $M^{\vee\vee} \longrightarrow M^{**}$ .

**13.35 Exercise.** Let  $R$  be a reduced Noetherian ring and assume that the normalization  $S$  is a finitely generated  $R$ -module. Let  $\mathfrak{c}$  be the conductor. Prove that  $S = \operatorname{End}_R(\mathfrak{c})$ .

**13.36 Exercise.** Let  $R$  and  $S$  be as in 13.7 and let  $N$  be a finitely generated  $S$ -module. Prove that  $\text{Hom}_S(\text{Hom}_S(N, S), S) \cong \text{Hom}_R(\text{Hom}_R(N, R), R)$ .

**13.37 Exercise.** Let  $R$  be a CM local ring and  $M$  a reflexive  $R$ -module which is locally free in codimension one. Let  $N$  be an arbitrary finitely generated  $R$ -module, and let  $M \cdot N$  denote the reflexive product of  $M$  and  $N$  (cf. Exercise 6.46). Show that  $M \cdot N \cong \text{Hom}_R(M^*, N)$ . Conclude that  $S \cdot N \cong \text{Hom}_R(\mathfrak{c}, N)$  in the setup 13.7.

**13.38 Exercise.** Prove Lemma 13.18, that the listed Burban-Drozd triples are a full set of representatives for the indecomposables of  $\text{BD}'(R)$ , along the following lines.

- The listed forms are pairwise non-isomorphic and cannot be further decomposed.
- Every object of  $\text{BD}'(R)$  splits into direct summands with either  $n = p = q$  or  $n = p + q$ . (Consider the complement of  $(\ker \theta_1) + \ker(\theta_2)$  in  $A^{(n)}$ .)
- In the case  $n = p + q$ , the object further splits into direct summands with either  $n = p$  or  $n = q$ . Any triple with  $n = p$  or  $n = q$  can be completely diagonalized, giving one of the factors of the normalization.

**13.39 Exercise.** Prove Lemma 13.20, that the listed Burban-Drozd triples are a full set of representatives for the indecomposables of  $\text{BD}'(R)$ , along the following lines.

- The listed forms are pairwise non-isomorphic and cannot be further decomposed.

- The  $m \times n$  matrix  $\theta$  can be reduced (using the rules of Lemma 13.20) to the block form

$$\begin{pmatrix} t^{d_1}I_{s_1} & A_{1,2} & \cdots & A_{1,v} & A_{1,v+1} \\ & t^{d_2}I_{s_2} & \cdots & A_{2,v} & A_{2,v+1} \\ & & \ddots & \vdots & \vdots \\ & & & t^{d_v}I_{s_v} & A_{v,v+1} \end{pmatrix}$$

where

- $d_1 < d_2 < \cdots < d_v$  and  $d_1 = 0$  or  $1$ .
- Each entry of  $A_{i,j}$  has order in  $t$  at least  $d_i + 1$  for  $1 \leq i \leq v$  and  $1 \leq j \leq v + 1$ .
- Each entry of  $A_{i,j}$  has order in  $t$  at most  $d_j$  for  $1 \leq i \leq v$  and  $1 \leq j \leq v$ .
- If  $A_{1,j} = 0$  for all  $j = 2, \dots, v + 1$ , then either (1) or (t) is a direct summand of  $\theta$  and we are done by induction on the number of rows.
- If  $A_{1,j} \neq 0$  for some  $j \leq v$ , write  $A_{1,j} = t^{d_1}B_{1,j}$  for some matrix  $B_{1,j}$  with entries in  $k[[t]]$ . Show that we may assume  $B_{1,j}$  has entries in  $k[[t^2]]$ , and then diagonalize over  $k[[t^2]]$  to assume  $B_{1,j} = \begin{pmatrix} I_{s'} & 0 \\ 0 & 0 \end{pmatrix}$ . If  $s' = 0$ , return to the previous step, while if  $s' > 0$ , split off one of

$$\begin{pmatrix} 1 & t \\ 0 & t^{d_j} \end{pmatrix} \quad \text{or} \quad \begin{pmatrix} t & t^2 \\ 0 & t^{d_j} \end{pmatrix}.$$

- Consider two cases for each of the above matrices:  $d_j = 1$  versus  $d_j \neq 1$  in the first matrix, and  $d_j = 2$  versus  $d_j \neq 2$  in the second. Split off one of the forms listed in Lemma 13.20 in each case.

- Finally, if  $A_{1,j} = 0$  for all  $j = 2, \dots, v$  but  $A_{1,v+1} \neq 0$ , then one of  $(1)$ ,  $(t)$ ,  $(1 \ t)$ , or  $(t \ t^2) \sim (1 \ t)$  is a direct summand of  $\theta$ .

**13.40 Exercise.** Generalize Lemma 5.11 as follows. Let  $R$  be a reduced ring satisfying Serre's condition  $(S_2)$ , and let  $f: M \rightarrow N$  be a homomorphism of  $R$ -modules, each of which satisfies  $(S_2)$ . Then  $f$  is an isomorphism if and only if  $f_{\mathfrak{p}}: M_{\mathfrak{p}} \rightarrow N_{\mathfrak{p}}$  is an isomorphism for every height-one prime  $\mathfrak{p}$  of  $R$ .

## *The Brauer-Thrall conjectures*

In a brief abstract published in the 1941 Bulletin of the AMS [Bra41], R. D. Brauer announced that he had found sufficient conditions for a finite-dimensional algebra  $A$  over a field  $k$  to have infinitely many non-isomorphic indecomposable finitely generated modules. Some years later, R. M. Thrall [Thr47] claimed similar results: he wrote that Brauer had in fact given three conditions, each sufficient to ensure that  $A$  has indecomposable modules of arbitrarily high  $k$ -dimension, and he gave a fourth sufficient condition. These were stated in terms of the so-called “Cartan invariants” [ANT44, p. 106] of the rings  $A$ ,  $A/\text{rad}(A)$ ,  $A/\text{rad}(A)^2$ , etc. Neither Brauer nor Thrall ever published the details of their work, leaving it to Thrall’s student J. P. Jans [Jan57] to publish them. Jans attributes to Brauer and Thrall the following conjectures. Let’s say that a finite-dimensional  $k$ -algebra  $A$  has *bounded representation type* if the  $k$ -dimensions of indecomposable finitely generated  $A$ -modules are bounded, and *strongly unbounded representation type* if  $A$  has infinitely many non-isomorphic modules of  $k$ -dimension  $n$  for infinitely many  $n$ .

**14.1 Conjecture** (Brauer-Thrall Conjectures). *Let  $A$  be a finite-dimensional algebra over a field  $k$ .*

- I. If  $A$  has bounded representation type then  $A$  actually has finite representation type.*
- II. Assume that  $k$  is infinite. If  $A$  has unbounded representation type, then  $A$  has strongly unbounded representation type.*

Both conjectures are now theorems. Brauer-Thrall I is due to A. V. Roĭter [Roĭ68], while Brauer-Thrall II was proved (as long as  $k$  is perfect) by L. A. Nazarova and Roĭter [NR73]. See [Rin80] or [Gus82] for some history on these results. (It's perhaps interesting to note that Auslander gave a proof of Roĭter's theorem for arbitrary Artinian rings [Aus74]—with length standing in for  $k$ -dimension—and that this is where “almost split sequences” made their first appearance.)

We import the definition of bounded type to the context of MCM modules almost verbatim. Recall that the *multiplicity* of a finitely generated module  $M$  over a local ring  $R$  is denoted  $e(M)$ .

**14.2 Definition.** We say that a CM local ring  $R$  has *bounded CM type* provided there is a bound on the multiplicities of the indecomposable MCM  $R$ -modules.

If an  $R$ -module  $M$  has constant rank  $r$ , then it is known that  $e(M) = r e(R)$  (see Appendix A, §2). Thus for modules with constant rank, a bound on multiplicities is equivalent to a bound on ranks.

The first example showing that that bounded and finite type are not equivalent in the context of MCM modules, that is, that Brauer-Thrall I fails, was given by Dieterich in 1980 [Die81]: Let  $k$  be a field of characteristic 2, let  $A = k[[x]]$ , and let  $G$  be the two-element group. Then the group ring  $AG$  has bounded but infinite CM type. Indeed, note that  $AG \cong k[[x, y]]/(y^2)$  (via the map sending the generator of the group to  $y-1$ ). Thus  $AG$  has multiplicity 2 but is analytically ramified, whence  $AG$  has bounded but infinite CM type by Theorem 4.18. In fact, as we saw in Chapter 13,  $k[[x, y]]/(y^2)$  has (countably) infinite CM type for every field  $k$ .

Theorem 4.10 says, in part, that if an analytically unramified local ring  $(R, \mathfrak{m}, k)$  of dimension one with infinite residue field  $k$  fails to have finite CM type, then  $R$  has  $|k|$  indecomposable MCM modules of every rank  $n$ . Thus, for these rings, finite CM type and bounded CM type are equivalent, just as for finite-dimensional algebras, and moreover Brauer-Thrall II even holds for these rings. In this chapter we present the proof, due independently to Dieterich [Die87] and Yoshino [Yos87], of Brauer-Thrall I for all complete, equicharacteristic, CM isolated singularities over a perfect field (Theorem 14.21) and show how to use the results of the previous chapters to weaken the hypothesis of completeness to that of excellence. We also give a new proof (independent of the one in Chapter 4) that Brauer-Thrall II holds for complete one-dimensional reduced rings with algebraically closed residue field (Theorem 14.28). The latter result uses Smalø's "inductive step" (Theorem 14.27) for building infinitely many indecomposables in a higher rank from infinitely many in a lower one. As another application of Smalø's theorem we observe that Brauer-Thrall II holds for rings of uncountable CM type.

## §1 The Harada-Sai lemma

We will reduce the proof of the first Brauer-Thrall conjecture to a statement about modules of finite length, namely the Harada-Sai Lemma 14.4. In this section we give Eisenbud-de la Peña's proof [EdlP98] of Harada-Sai, and in the next section we show how to extend it to MCM modules. The Lemma gives an upper bound on the lengths of non-zero paths in the Auslander-

Reiten quiver. To state it, we make a definition.

**14.3 Definition.** Let  $R$  be a commutative ring and let

$$(14.3.1) \quad M_1 \xrightarrow{f_1} M_2 \xrightarrow{f_2} \cdots \xrightarrow{f_{s-1}} M_s$$

be a sequence of homomorphisms between  $R$ -modules. We say (14.3.1) is a *Harada-Sai sequence* if

- (i) each  $M_i$  is indecomposable of finite length;
- (ii) no  $f_i$  is an isomorphism; and
- (iii) the composition  $f_{s-1}f_{s-2}\cdots f_1$  is non-zero.

Fitting's Lemma (Exercise 1.25) implies that, in the special case where  $M_i = M$  and  $f_i = f$  are constant for all  $i$ , the longest possible Harada-Sai sequence has length  $\ell(M) - 1$ , where as usual  $\ell(M)$  denotes the length of  $M$ . In general, the Harada-Sai Lemma gives a bound on the length of a Harada-Sai sequence in terms of the lengths of the modules.

**14.4 Lemma.** *Let (14.3.1) be a Harada-Sai sequence with the length of each  $M_i$  bounded above by  $b$ . Then  $s \leq 2^b - 1$ .*

In fact we will prove a more precise statement, which determines exactly which sequences of lengths  $\ell(M_i)$  are possible in a Harada-Sai sequence.

**14.5 Definition.** The *length sequence* of a sequence (14.3.1) of modules of finite length is the integer sequence  $\underline{\lambda} = (\ell(M_1), \ell(M_2), \dots, \ell(M_s))$ .

We define *special* integer sequences as follows:

$$\lambda^{(1)} = (1)$$

$$\lambda^{(2)} = (2, 1, 2)$$

$$\lambda^{(3)} = (3, 2, 3, 1, 3, 2, 3)$$

and, in general,  $\lambda^{(b)}$  is obtained by inserting  $b$  at the beginning, the end, and between every two entries of  $\lambda^{(b-1)}$ . Alternatively,

$$\lambda^{(b+1)} = (\lambda^{(b)} + \mathbf{1}, 1, \lambda^{(b)} + \mathbf{1}),$$

where  $\mathbf{1}$  is the sequence of all 1s. Notice that  $\lambda^{(b)}$  is a list of  $2^b - 1$  integers.

We say that one integer sequence  $\lambda$  of length  $n$  *embeds* in another integer sequence  $\mu$  of length  $m$  if there is a strictly increasing function  $\sigma: \{1, \dots, n\} \rightarrow \{1, \dots, m\}$  such that  $\lambda_i = \mu_{\sigma(i)}$ .

Lemma 14.4 follows from the next result.

**14.6 Theorem.** *There is a Harada-Sai sequence with length sequence  $\underline{\lambda}$  if and only if  $\underline{\lambda}$  embeds in  $\lambda^{(b)}$  for some  $b$ .*

*Proof.* First let

$$(14.6.1) \quad M_1 \xrightarrow{f_1} M_2 \xrightarrow{f_2} \dots \xrightarrow{f_{s-1}} M_s$$

be a Harada-Sai sequence with length sequence  $\underline{\lambda} = (\lambda_1, \dots, \lambda_s)$ . Set  $b = \max\{\lambda_i\}$ . If  $b = 1$ , then each  $M_i$  is simple. As the composition is non-zero and no  $f_i$  is an isomorphism, the length of the sequence must be 1. Thus  $\underline{\lambda} = (1)$  embeds in  $\lambda^{(1)} = (1)$ .

Suppose then that  $b > 1$ . If two consecutive entries of  $\underline{\lambda}$  are both equal to  $b$ , say  $\lambda_i = \lambda_{i+1} = b$ , then we may insert some indecomposable summand

of  $\text{im}(f_i)$  between  $M_i$  and  $M_{i+1}$ , chosen so that the composition is still non-zero. This gives a new Harada-Sai sequence, one step longer. Thus we may assume that no two consecutive  $\lambda_i$  are equal to  $b$ .

Observe that any sub-composition  $g = f_j f_{j-1} \cdots f_i: M_i \rightarrow M_{j+1}$ , with  $i \leq j$ , is a non-isomorphism. Indeed, if  $g$  were an isomorphism, then  $f_i: M_i \rightarrow M_{i+1}$  would be injective, so that  $\ell(M_{i+1}) > \ell(M_i)$ . Then

$$M_i \xrightarrow{f_i} M_{i+1} \xrightarrow{f_j f_{j-1} \cdots f_{i+1}} M_j \xrightarrow{g^{-1}} M_i$$

is the identity on  $M_i$ , so  $f_i$  is a split monomorphism. This contradicts the indecomposability of  $M_{i+1}$ .

Let  $\underline{\lambda}'$  be the integer sequence gotten from  $\underline{\lambda}$  by deleting every occurrence of  $b$ . Then  $\underline{\lambda}'$  is the length sequence of the Harada-Sai sequence obtained by “collapsing” (14.6.1): for each  $M_i$  having length equal to  $b$ , delete  $M_i$  and replace the pair of homomorphisms  $f_i$  and  $f_{i+1}$  by the composition  $f_{i+1} f_i: M_{i-1} \rightarrow M_{i+1}$ . By induction  $\underline{\lambda}'$  embeds into  $\lambda^{(b-1)}$ . Since every second element of  $\lambda^{(b)}$  is  $b$  and the  $b$ 's in  $\underline{\lambda}$  never repeat, this can be extended to an embedding  $\underline{\lambda} \rightarrow \lambda^{(b)}$ .

For the other direction, it suffices by the same “collapsing” argument to show that there is a Harada-Sai sequence with length sequence equal to  $\lambda^{(b)}$ . We state this separately as Example 14.7 below. □

**14.7 Example.** There is a Harada-Sai sequence with length sequence  $\lambda^{(b)}$  for every  $b \geq 1$ . We construct examples over the ring  $R = k[x, y]/(xy)$ , where  $k$  is an arbitrary field, following [EdlP98].

For any (non-commutative) word  $\omega$  in the symbols  $x$  and  $y$ , we build an indecomposable  $R$ -module  $M(\omega)$  of length one more than the length of  $\omega$ .

Let  $M(\omega)$  be the vector space spanned by basis vectors  $e_a$ , one for each letter  $a \in \{x, y\}$  in  $\omega$ , together with an additional distinguished basis element  $\star$ . Let  $s(a)$  denote the successor of  $a$  in  $\omega$ , and  $p(a)$  the predecessor; we interpret  $\star$  as the last letter of  $\omega$ , so that  $p(\star)$  is the last  $x$  or  $y$  appearing in  $\omega$ , and  $s(\star)$  is empty. Define the  $R$ -module structure on the elements  $e_a \in M(\omega)$  by

$$ye_a = \begin{cases} e_{s(a)} & \text{if } a = y, \text{ and} \\ 0 & \text{otherwise,} \end{cases} \quad xe_a = \begin{cases} e_{p(a)} & \text{if } p(a) = x, \text{ and} \\ 0 & \text{otherwise.} \end{cases}$$

Further define  $x\star$  to be the last  $x$  or  $y$  appearing in  $\omega$ , and finally set  $y\star = 0$ . Note two things: that in particular  $xy$  and  $yx$  both annihilate all basis vectors  $e_a$  and  $\star$ , so that  $M(\omega)$  is an  $R$ -module, and that  $\star \notin xM(\omega)$ .

For example, if  $\omega = 1$  is the empty word, then  $M(\omega)$  is the simple  $R$ -module generated by  $\star$ .

Here is an example to clarify. Suppose  $\omega = yx^2y^2x^3$ ; then  $M(\omega)$  has 9 basis vectors, which we represent by bullets and  $\star$ , and the multiplication table is given by the following “string diagram.”

For the example, it is clear that  $M(yx^2y^2x^3)$  is indecomposable, since the string diagram is connected. In general, the same observation suffices to see that  $M(\omega)$  is indecomposable for all  $\omega$ .

We will construct inductively Harada-Sai sequences  $\epsilon_b$  with length sequence  $\lambda^{(b)}$ . Every homomorphism in these sequences will take basis ele-

ments to basis elements; in particular, they will take  $\star$  to  $\star$ , so the composition will be non-zero. For  $b = 1$ , take  $\epsilon_1$  to be the trivial sequence with a single module  $M(1)$ .

Suppose  $\epsilon_b$  has the form

$$\epsilon_b: M(\omega_1) \longrightarrow M(\omega_2) \longrightarrow \cdots \longrightarrow M(\omega_{2^b-1})$$

where the lengths of  $M(\omega_i)$  are given by the sequence  $\lambda^{(b)}$  and each map takes  $\star$  to  $\star$ . Observe that for any  $\omega$ , the module  $M(\omega)$  is naturally a submodule of  $M(\omega x)$ , where we take the new  $\star$  to be the newly added basis element. If  $f: M(\eta) \longrightarrow M(\omega)$  is a homomorphism taking  $\star$  to  $\star$ , then  $f$  naturally extends to  $\tilde{f}: M(\eta x) \longrightarrow M(\omega x)$ , taking the new  $\star$  to the new  $\star$ . Applying this operation to  $\epsilon_b$  yields

$$\tilde{\epsilon}_b: M(\omega_1 x) \longrightarrow M(\omega_2 x) \longrightarrow \cdots \longrightarrow M(\omega_{2^b-1} x) \longrightarrow \cdots \longrightarrow M(\omega_{2^b-1} x).$$

Since the  $(2^{b-1})^{\text{th}}$  entry of  $\lambda^{(b)}$  is 1, we see that  $\omega_{2^b-1}$  was the empty word 1, so that  $\omega_{2^b-1} x = x$ . We truncate  $\tilde{\epsilon}_b$  at  $M(\omega_{2^b-1} x) = M(x)$ , dropping the right-hand half.

Next, observe that  $R$  admits a  $k$ -algebra automorphism defined by interchanging  $x$  and  $y$ ; this also induces a map on words  $\omega$ , sending  $\omega$  to, say,  $\hat{\omega}$ . Again, if  $f: M(\eta) \longrightarrow M(\omega)$  is a homomorphism preserving  $\star$ , then we obtain  $\hat{f}: M(\hat{\omega}) \longrightarrow M(\hat{\eta})$  with  $\hat{f}(\star) = \star$ . Following this inversion with the  $\tilde{?}$  operation described above gives

$$\hat{\epsilon}_b: M(\hat{\omega}_{2^b-1} x) \longrightarrow \cdots \longrightarrow M(\hat{\omega}_{2^b-1} x) \longrightarrow \cdots \longrightarrow M(\hat{\omega}_2 x) \longrightarrow M(\hat{\omega}_1 x).$$

We again truncate at the  $(2^{b-1})^{\text{th}}$  stage, this time dropping the left-hand

half, and define  $\alpha$  to be the sequence

$$\begin{array}{ccccccc}
 M(\omega_1 x) & \longrightarrow & M(\omega_2 x) & \longrightarrow & \cdots & \longrightarrow & M(\omega_{2^{b-1}} x) \\
 & & & & & & \parallel \\
 & & & & & & M(x) \\
 & & & & & & \parallel \\
 & & & & & & M(\hat{\omega}_{2^{b-1}} x) & \longrightarrow & \cdots & \longrightarrow & M(\hat{\omega}_2 x) & \longrightarrow & M(\hat{\omega}_1 x).
 \end{array}$$

As each homomorphism in the sequence  $\alpha$  takes  $\star$  to  $\star$ , and  $\star$  is outside the radical of each module, we may extend  $\alpha$  one step to the right, with the map  $M(\hat{\omega}_1 x) \rightarrow M(1)$  sending  $\star$  to  $\star$  and killing all the other basis elements.

Finally, the  $k$ -vector space dual  $-^\vee = \text{Hom}_k(-, k)$  is a functor on  $R$ -modules. We take the distinguished element of  $\text{Hom}_k(M(\omega), k)$  to be the dual basis element corresponding to the distinguished element  $\star$  of  $M(\omega)$ . We have  $M(1)^\vee \cong M(1)$ , so we may splice  $\alpha$  together with  $\alpha^\vee$  to obtain

$$\epsilon_{b+1}: \alpha \rightarrow M(1) \cong M(1)^\vee \rightarrow \alpha^\vee$$

which has length vector  $(\lambda^{(b)} + \mathbf{1}, 1, \lambda^{(b)} + \mathbf{1}) = \lambda^{(b+1)}$ .

## §2 Faithful systems of parameters

The goal of this section is to prove an analogue of the Harada-Sai Lemma 14.4 for MCM modules. We will reduce to the case of finite-length modules by killing a particularly nice regular sequence: one that preserves indecomposability, non-isomorphism, and even non-split short exact sequences of MCM modules.

Throughout,  $(R, \mathfrak{m}, k)$  is a CM local ring of dimension  $d$ . We will need to impose additional restrictions later on; see Theorem 14.20 for the full list.

**14.8 Definition.** Let  $\mathbf{x} = x_1, \dots, x_d$  be a system of parameters for  $R$ . We say  $\mathbf{x}$  is a *faithful* system of parameters if  $\mathbf{x}$  annihilates  $\text{Ext}_R^1(M, N)$  for every pair of  $R$ -modules with  $M$  MCM.

In what follows, we write  $\mathbf{x}^2$  for the system of parameters  $x_1^2, \dots, x_d^2$ . Here is the basic property of faithful systems of parameters that makes them well suited to our purposes.

**14.9 Proposition.** *Let  $\mathbf{x} = x_1, \dots, x_d$  be a faithful system of parameters, and let  $M$  and  $N$  be MCM  $R$ -modules. For every homomorphism  $\varphi: M/\mathbf{x}^2M \rightarrow N/\mathbf{x}^2N$ , there exists  $\tilde{\varphi} \in \text{Hom}_R(M, N)$  such that  $\varphi$  and  $\tilde{\varphi}$  induce the same homomorphism  $M/\mathbf{x}M \rightarrow N/\mathbf{x}N$ .*

It's interesting to observe the similarity of this statement to Guralnick's Lemma 1.12. The statement could even be given the same form: a commutative rectangle consisting of two squares, the bottom of which also commutes, though the top square might not.

*Proof.* Our goal is the case  $i = 0$  of the following statement: there exists a homomorphism

$$\varphi_i: M/(x_1^2, \dots, x_i^2)M \rightarrow N/(x_1^2, \dots, x_i^2)N$$

such that  $\varphi_i \otimes_R R/(\mathbf{x}) = \varphi \otimes_R R/(\mathbf{x})$ . We prove this by descending induction on  $i$ , taking  $\varphi_d = \varphi$  for the base case  $i = d$ .

Assume that  $\varphi_{i+1}$  has been constructed. Then it suffices to find a homomorphism  $\varphi_i : M/(x_1^2, \dots, x_i^2)M \rightarrow N/(x_1^2, \dots, x_i^2)N$  with the following stronger property:

$$\varphi_i \otimes_R R/(x_1^2, \dots, x_i^2, x_{i+1}) = \varphi \otimes_R R/(x_1^2, \dots, x_i^2, x_{i+1}),$$

for then of course killing  $x_1, \dots, x_i, x_{i+2}, \dots, x_d$  we obtain  $\varphi_i \otimes_R R/(\mathbf{x}) = \varphi \otimes_R R/(\mathbf{x})$ .

Set  $\mathbf{y}_i = x_1^2, \dots, x_i^2$  and  $\mathbf{z}_i = x_1^2, \dots, x_i^2, x_{i+1}$ . Then we have a commutative diagram with exact rows (as  $N$  is MCM and  $x_{i+1}$  is an  $R$ -regular element)

$$\begin{array}{ccccccc} 0 & \longrightarrow & N/\mathbf{y}_i N & \xrightarrow{x_{i+1}^2} & N/\mathbf{y}_i N & \longrightarrow & N/\mathbf{y}_{i+1} N \longrightarrow 0 \\ & & \downarrow x_{i+1} & & \parallel & & \downarrow \\ 0 & \longrightarrow & N/\mathbf{y}_i N & \xrightarrow{x_{i+1}} & N/\mathbf{y}_i N & \longrightarrow & N/\mathbf{z}_i N \longrightarrow 0. \end{array}$$

Apply  $\text{Hom}_R(M, -)$  to obtain a commutative exact diagram

$$\begin{array}{ccccc} \text{Hom}_R(M, N/\mathbf{y}_i N) & \longrightarrow & \text{Hom}_R(M, N/\mathbf{y}_{i+1} N) & \longrightarrow & \text{Ext}_R^1(M, N/\mathbf{y}_i N) \\ \parallel & & \downarrow & & \downarrow x_{i+1} \\ \text{Hom}_R(M, N/\mathbf{y}_i N) & \longrightarrow & \text{Hom}_R(M, N/\mathbf{z}_i N) & \longrightarrow & \text{Ext}_R^1(M, N/\mathbf{y}_i N). \end{array}$$

By the definition of a faithful system of parameters, the right-hand vertical map is zero. We have  $\varphi_{i+1}$  living in  $\text{Hom}_R(M, N/\mathbf{y}_{i+1} N)$  in the middle of the top row, and an easy diagram chase delivers  $\varphi_i$  in the top-left corner such that  $\varphi_i \otimes_R R/(\mathbf{z}_i) \cong \varphi_{i+1} \otimes_R R/(\mathbf{z}_i)$ .  $\square$

Here are the main consequences of Proposition 14.9. The first and third corollaries are sometimes called “Maranda’s Theorem,” having first been proven by Maranda [Mar53] in the case of the group ring of a finite group over the ring of  $p$ -adic integers, and extended by Higman [Hig60] to arbitrary orders over complete discrete valuation rings.

**14.10 Corollary.** *Let  $\mathbf{x}$  be a faithful system of parameters for  $R$ , and let  $M$  and  $N$  be MCM  $R$ -modules. Suppose that  $\varphi: M/\mathbf{x}^2M \rightarrow N/\mathbf{x}^2N$  is an isomorphism. Then there exists an isomorphism  $\tilde{\varphi}: M \rightarrow N$  such that  $\tilde{\varphi} \otimes_R R/(\mathbf{x}) = \varphi \otimes_R R/(\mathbf{x})$ .*

*Proof.* Proposition 14.9 gives us the homomorphism  $\tilde{\varphi}$ ; it remains to see that  $\tilde{\varphi}$  is an isomorphism. Since  $\tilde{\varphi}$  is surjective modulo  $\mathbf{x}^2$ , it is at least surjective by NAK. Similarly, applying the Proposition to  $\varphi^{-1}$ , we find that there is a surjection  $\widetilde{\varphi^{-1}}: N \rightarrow M$ . By Exercise 4.25, the surjection  $\widetilde{\varphi^{-1}}\tilde{\varphi}: M \rightarrow M$  is an isomorphism, so  $\tilde{\varphi}$  is as well.  $\square$

**14.11 Corollary.** *Let  $\mathbf{x}$  be a faithful system of parameters for  $R$ , and let  $s: 0 \rightarrow N \xrightarrow{i} E \xrightarrow{p} M \rightarrow 0$  be a short exact sequence of MCM modules. Then  $s$  is non-split if and only if  $s \otimes_R R/(\mathbf{x}^2)$  is non-split.*

*Proof.* Sufficiency is clear: a splitting for  $s$  immediately gives a splitting for  $s \otimes_R R/(\mathbf{x}^2)$ . For the other direction, suppose  $\bar{p} = p \otimes_R R/(\mathbf{x}^2)$  is a split epimorphism. Then there exists  $\varphi: M/\mathbf{x}^2M \rightarrow E/\mathbf{x}^2E$  such that  $\bar{p}\varphi$  is the identity on  $M/\mathbf{x}^2M$ . Let  $\tilde{\varphi}: M \rightarrow E$  be the lifting guaranteed by Proposition 14.9. Then  $(p\tilde{\varphi}) \otimes_R R/(\mathbf{x})$  is the identity on  $M/\mathbf{x}M$ , so  $p\tilde{\varphi}$  is an isomorphism. Thus  $s$  is split.  $\square$

**14.12 Corollary.** *Assume that  $R$  is Henselian. Let  $\mathbf{x}$  be a faithful system of parameters for  $R$ , and let  $M$  be a MCM  $R$ -module. Then  $M$  is indecomposable if and only if  $M/\mathbf{x}^2M$  is indecomposable.*

*Proof.* Again, we have only to prove one direction: if  $M$  decomposes non-trivially, then so must  $M/\mathbf{x}^2M$  by NAK. For the other direction, assume

that  $M$  is indecomposable. Then  $\text{End}_R(M)$  is a nc-local ring since  $R$  is Henselian (see Chapter 1). We have a commutative diagram

$$\begin{array}{ccc} \text{End}_R(M) & \longrightarrow & \text{End}_R(M/\mathbf{x}^2M) \\ & \searrow \tau & \swarrow \pi \\ & \text{End}_R(M/\mathbf{x}M) & \end{array}$$

where each map is the natural one induced by tensoring with  $R/(\mathbf{x})$  or  $R/(\mathbf{x}^2)$ . Let  $e \in \text{End}_R(M/\mathbf{x}^2M)$  be an idempotent; we'll show that  $e$  is either 0 or 1, so that  $M/\mathbf{x}^2M$  is indecomposable. The image  $\pi(e)$  of  $e$  in  $\text{End}_R(M/\mathbf{x}M)$  is still idempotent, and is contained in  $\tau(\text{End}_R(M))$  by Proposition 14.9. Since  $\text{End}_R(M)$  is nc-local, so is its homomorphic image  $\tau(\text{End}_R(M))$ , so  $\pi(e)$  is either 0 or 1.

If  $\pi(e) = 0$ , then  $e \otimes_R R/(\mathbf{x}) = 0$ , so that  $e(M/\mathbf{x}^2M) \subseteq \mathbf{x}(M/\mathbf{x}^2M)$ . But  $e$  is idempotent, so that  $\text{im}(e) = \text{im}(e^2) \subseteq \text{im}(\mathbf{x}^2) = 0$  and so  $e = 0$ . If  $\pi(e) = 1$ , then the same argument applies to  $1 - e$ , giving  $e = 1$ .  $\square$

To address the existence of faithful systems of parameters, consider a couple of general lemmas. We leave the proof of the first as an exercise. The second is an easy special case of [Wan94, Lemma 5.10].

**14.13 Lemma.** *Let  $\Gamma$  be a ring,  $I$  an ideal of  $\Gamma$ , and  $\Lambda = \Gamma/I$ . Then  $\text{Ann}_\Gamma I$  annihilates  $\text{Ext}_\Gamma^1(\Lambda, K)$  for every  $\Gamma$ -module  $K$ .*

**14.14 Lemma.** *Let  $\Gamma$  be a ring,  $I$  an ideal of  $\Gamma$ , and  $\Lambda = \Gamma/I$ . Let*

$$(14.14.1) \quad L \xrightarrow{\varphi} M \xrightarrow{\psi} N$$

*be an exact sequence of  $\Gamma$ -modules. Then the homology  $H$  of the complex*

$$(14.14.2) \quad \text{Hom}_\Gamma(\Lambda, L) \xrightarrow{\varphi^*} \text{Hom}_\Gamma(\Lambda, M) \xrightarrow{\psi^*} \text{Hom}_\Gamma(\Lambda, N)$$

is annihilated by  $\text{Ann}_\Gamma I$ .

*Proof.* Let  $K = \ker \varphi$  and  $X = \text{im } \varphi$ , and let  $\eta: L \rightarrow X$  be the surjection induced by  $\varphi$ . Then applying  $\text{Hom}_\Gamma(\Lambda, -)$ , we see that the cohomology of (14.14.2) is equal to the cokernel of  $\text{Hom}_\Gamma(\Lambda, \eta): \text{Hom}_\Gamma(\Lambda, L) \rightarrow \text{Hom}_\Gamma(\Lambda, X)$ . This cokernel is also a submodule of  $\text{Ext}_\Gamma^1(\Lambda, K)$ , so we are done by the previous lemma.  $\square$

We will apply Lemma 14.14 to the *homological different*  $\mathfrak{H}_T(R)$  of a homomorphism  $T \rightarrow R$ , where  $R$  is as above a CM local ring and  $T$  is a regular local ring. Recall from Appendix B that if  $A \rightarrow B$  is a homomorphism of commutative rings, we let  $\mu: B \otimes_A B \rightarrow B$  be the multiplication map defined by  $\mu(b \otimes b') = bb'$ , and we set  $\mathcal{J} = \ker \mu$ . The homological different  $\mathfrak{H}_A(B)$  is then defined to be

$$\mathfrak{H}_A(B) = \mu(\text{Ann}_{B \otimes_A B} \mathcal{J}).$$

Notice that for any two  $B$ -module  $M$  and  $N$ ,  $\text{Hom}_A(M, N)$  is naturally a  $B \otimes_A B$ -module via the rule  $[\varphi(b \otimes b')](m) = \varphi(bm)b'$  for any  $\varphi \in \text{Hom}_A(M, N)$ ,  $m \in M$ , and  $b, b' \in B$ . Since for any  $B \otimes_A B$ -module  $X$ ,  $\text{Hom}_{B \otimes_A B}(R, X)$  is the submodule of  $X$  annihilated by  $\mathcal{J}$ , and  $\mathcal{J}$  is generated by elements of the form  $b \otimes 1 - 1 \otimes b$ , we see that

$$\text{Hom}_{B \otimes_A B}(B, \text{Hom}_A(M, N)) = \text{Hom}_B(M, N)$$

for all  $M, N$ . Thus in particular  $\text{Hom}_B(M, N)$  is a  $B \otimes_A B$ -module as well, with structure via the map  $\mu$ .

**14.15 Proposition.** *Let  $R$  be a CM local ring and let  $T \subseteq R$  be a regular local ring such that  $R$  is a finitely generated  $T$ -module. Then  $\mathfrak{H}_T(R)$  annihilates  $\text{Ext}_R^1(M, N)$  for every MCM  $R$ -module  $M$  and arbitrary  $R$ -module  $N$ .*

*Proof.* Let  $0 \rightarrow N \rightarrow I^0 \rightarrow I^1 \rightarrow I^2 \rightarrow \dots$  be an injective resolution of  $N$  over  $R$ . Since  $M$  is MCM over  $R$ , it is finitely generated and free over  $T$ , and the complex

$$\text{Hom}_T(M, I^0) \xrightarrow{\varphi} \text{Hom}_T(M, I^1) \xrightarrow{\psi} \text{Hom}_T(M, I^2)$$

is exact. Apply  $\text{Hom}_{R \otimes_T R}(R, -)$ ; by the discussion above the result is

$$\text{Hom}_R(M, I^0) \xrightarrow{\varphi^*} \text{Hom}_R(M, I^1) \xrightarrow{\psi^*} \text{Hom}_R(M, I^2).$$

The homology  $H$  of this complex is naturally  $\text{Ext}_R^1(M, N)$ , and is by Lemma 14.14 annihilated by  $\text{Ann}_{R \otimes_T R} \mathcal{J}$ . Since the  $R \otimes_T R$ -module structure on these Hom modules is via  $\mu$ , we see that  $\mathfrak{H}_T(R) = \mu(\text{Ann}_{R \otimes_T R} \mathcal{J})$  annihilates  $\text{Ext}_R^1(M, N)$ .  $\square$

Put  $\mathfrak{H}(R) = \sum_T \mathfrak{H}_T(R)$ , where the sum is over all regular local subrings  $T$  of  $R$  such that  $R$  is a finitely generated  $T$ -module. It follows immediately from Proposition 14.15 that  $\mathfrak{H}(R)$  annihilates  $\text{Ext}_R^1(M, N)$  whenever  $M$  is MCM.

Let us now introduce a more classical ideal, the Jacobian. Let  $T$  be a Noetherian ring and  $R$  a finitely generated  $T$ -algebra. Then  $R$  has a presentation  $R = T[x_1, \dots, x_n]/(f_1, \dots, f_m)$  for some  $n$  and  $m$ . The *Jacobian ideal of  $R$  over  $T$*  is the ideal  $J_T(R)$  in  $R$  generated by the  $n \times n$  minors of

the Jacobian matrix  $(\partial f_i / \partial x_j)_{ij}$ . We set  $J(R) = \sum_T J_T(R)$ , where again the sum is over all regular subrings  $T$  of  $R$  over which  $R$  is module-finite.

One can see ([Wan94, Prop. 5.8] or Exercise 14.35) that  $J_T(R) \subseteq \mathfrak{h}_T(R)$  for every  $T$ , so that  $J(R) \subseteq \mathfrak{h}(R)$ . Thus we have

**14.16 Corollary.** *Let  $R$  be a CM local ring and let  $J(R)$  be the Jacobian ideal of  $R$ . Then  $J$  annihilates  $\text{Ext}_R^1(M, N)$  for every pair of  $R$ -modules  $M, N$  with  $M$  MCM.*

There are two problems with this result. The first is the question of whether any regular local subrings  $T$  as in the definition of  $J(R)$  actually exist. Luckily, Cohen's structure theorems assure us that when  $R$  is complete and contains its residue field  $k$ , there exist plenty of regular local rings  $T = k[[x_1, \dots, x_d]]$  over which  $R$  is module-finite.

The second problem is that  $J(R)$  may be trivial if the residue field is not perfect.

**14.17 Remark.** If  $R = T[x]/(f(x))$ , then it is easy to see that  $J_T(R)$  is the ideal of  $R$  generated by the derivative  $f'(x)$ . Thus in the case when  $R$  is a hypersurface  $R = k[[x_1, \dots, x_d]]$ ,  $J(R)$  is the ideal of  $R$  generated by the partial derivatives  $\partial f / \partial x_i$  of  $f$ . If  $k$  is not perfect, this ideal can be zero.

For example, suppose that  $k$  is an imperfect field of characteristic  $p$ , and let  $\alpha \in k \setminus k^p$ . Put  $R = k[[x, y]]/(x^p - \alpha y^p)$ . Then  $J(R) = 0$ . Note that  $R$  is a one-dimensional domain, so is an isolated singularity. Thus in particular  $J$  does not define the singular locus of  $R$ .

To address this second problem, we appeal to Nagata's Jacobian Criterion for smoothness of complete local rings [GD64, 22.7.2] (see also [Wan94,

Props. 4.4 and 4.5]).

**14.18 Theorem.** *Let  $(R, \mathfrak{m}, k)$  be an equidimensional complete local ring containing its residue field  $k$ . Assume that  $k$  is perfect. Then the Jacobian ideal  $J(R)$  of  $R$  defines the singular locus: for a prime ideal  $\mathfrak{p}$ ,  $R_{\mathfrak{p}}$  is a regular local ring if and only if  $J(R) \not\subseteq \mathfrak{p}$ .*

This immediately gives existence of faithful systems of parameters, and our extension of the Harada-Sai Lemma to MCM modules. We leave the details of the proof of existence as an exercise (Exercise 14.36).

**14.19 Theorem** (Yoshino). *Let  $(R, \mathfrak{m}, k)$  be a complete CM local ring containing its residue field  $k$ . Assume that  $k$  is perfect and that  $R$  has an isolated singularity. Then  $R$  admits a faithful system of parameters.*

**14.20 Theorem** (Harada-Sai for MCM modules). *Let  $R$  be an equicharacteristic complete CM local ring with perfect residue field and an isolated singularity. Let  $\mathbf{x}$  be a faithful system of parameters for  $R$ . Let  $M_0, M_1, \dots, M_{2^n}$  be indecomposable MCM  $R$ -modules, and let  $f_i: M_i \rightarrow M_{i+1}$  be homomorphisms that are not isomorphisms. If  $\ell(M_i/\mathbf{x}^2 M_i) \leq n$  for all  $i = 0, \dots, 2^n$ , then  $f_{2^n-1} \cdots f_2 f_1 \otimes_R R/(\mathbf{x}^2) = 0$ .*

*Proof.* Set  $\widetilde{M}_i = M_i/\mathbf{x}^2 M_i$  and  $\widetilde{f}_i = f_i \otimes_R R/(\mathbf{x}^2)$ . Then  $\widetilde{M}_0 \xrightarrow{\widetilde{f}_0} \dots \xrightarrow{\widetilde{f}_{2^n-1}} \widetilde{M}_{2^n}$  is a sequence of indecomposable modules, each with length at most  $n$ , in which no  $\widetilde{f}_i$  is an isomorphism. It is too long to be a Harada-Sai sequence, however, so we conclude  $f_{2^n} \cdots f_2 f_1 \otimes_R R/(\mathbf{x}^2) = 0$ .  $\square$

### §3 Proof of Brauer-Thrall I

We're now ready for the proof of the following theorem, proved independently in the complete case by Dieterich [Die87] and Yoshino [Yos87]. See also [PR90] and [Wan94].

**14.21 Theorem.** *Let  $(R, \mathfrak{m}, k)$  be an excellent equicharacteristic CM local ring with algebraically closed residue field  $k$ . Then  $R$  has finite CM type if and only if  $R$  has bounded CM type and at most an isolated singularity.*

Of course one direction of the theorem follows immediately from Auslander's Theorem 7.12, and requires no hypotheses apart from Cohen-Macaulayness. The content of the theorem is that bounded type and isolated singularity together imply finite type.

We begin by considering the complete case, and at the end of the section we show how to relax this restriction. When the residue field  $k$  is algebraically closed and  $R$  is complete and has at most an isolated singularity, we have access to the Auslander-Reiten quiver of  $R$ , as well as to faithful systems of parameters. In this case, we will prove

**14.22 Theorem.** *Let  $(R, \mathfrak{m}, k)$  be a complete equicharacteristic CM local ring with algebraically closed residue field  $k$ . Assume that  $R$  has at most an isolated singularity. Let  $\Gamma$  be the AR quiver of  $R$  and  $\Gamma^\circ$  a non-empty connected component of  $\Gamma$ . If there exists an integer  $B$  such that  $e(M) \leq B$  for all  $[M] \in \Gamma^\circ$ , then  $\Gamma = \Gamma^\circ$  and  $\Gamma$  is finite. In particular  $R$  has finite CM type.*

Let us be precise about what it means for  $\Gamma^\circ$  to be a connected component. We take it to mean that  $\Gamma^\circ$  is *closed under irreducible homomorphisms*, meaning that if  $X \rightarrow Y$  is an irreducible homomorphism between indecomposable MCM modules, then  $[X] \in \Gamma^\circ$  if and only if  $[Y] \in \Gamma^\circ$ .

Here is the strategy of the proof. Assume that  $\Gamma^\circ$  is a connected component of  $\Gamma$  with bounded multiplicities. We will show that for any  $[M]$  and  $[N]$  in  $\Gamma$ , if either of  $[M]$  or  $[N]$  is in  $\Gamma^\circ$  then there is a path from  $[M]$  to  $[N]$  in  $\Gamma$ , and furthermore that such a path can be chosen to have bounded length. To do this, we assume no such path exists and derive a contradiction to the Harada-Sai Lemma 14.20.

We fix notation as in Theorem 14.22:  $(R, \mathfrak{m}, k)$  is a complete equicharacteristic CM local ring with algebraically closed residue field  $k$  and with an isolated singularity. Let  $\Gamma$  be the AR quiver of  $R$ . By Theorem 14.19 there exists a faithful system of parameters  $\mathbf{x}$  for  $R$ . We say that a homomorphism  $\varphi: M \rightarrow N$  between  $R$ -modules is non-trivial modulo  $\mathbf{x}^2$  if  $\varphi \otimes_R R/(\mathbf{x}^2) \neq 0$ . Abusing notation slightly, we also say that a path in  $\Gamma$  is non-trivial modulo  $\mathbf{x}^2$  if the corresponding composition of irreducible maps is non-trivial modulo  $\mathbf{x}^2$ .

**14.23 Lemma.** *Fix a non-negative integer  $n$ . Let  $M$  and  $N$  be indecomposable MCM  $R$ -modules and  $\varphi: M \rightarrow N$  a homomorphism which is non-trivial modulo  $\mathbf{x}^2$ . Assume that there is no directed path in  $\Gamma$  from  $[M]$  to  $[N]$  of length  $< n$  which is non-trivial modulo  $\mathbf{x}^2$ . Then the following two statements hold.*

(i) *There is a sequence of homomorphisms*

$$M = M_0 \xrightarrow{f_1} M_1 \xrightarrow{f_2} \dots \xrightarrow{f_n} M_n \xrightarrow{g} N$$

*with each  $M_i$  indecomposable, each  $f_i$  irreducible, and the composition  $gf_n \cdots f_1$  non-trivial modulo  $\mathbf{x}^2$ .*

(ii) *There is a sequence of homomorphisms*

$$M \xrightarrow{h} N_n \xrightarrow{g_n} N_{n-1} \xrightarrow{g_{n-1}} \dots \xrightarrow{g_1} N_0 = N$$

*with each  $N_i$  indecomposable, each  $g_i$  irreducible, and the composition  $g_1 \cdots g_n h$  non-trivial modulo  $\mathbf{x}^2$ .*

*Proof.* We prove part (ii); the other half is similar.

If  $n = 0$ , then we may simply take  $h = \varphi: M \rightarrow N$ . Assume therefore that  $n > 0$ , there is no directed path of length  $< n$  from  $[M]$  to  $[N]$  which is non-trivial modulo  $\mathbf{x}^2$ , and that we have constructed a sequence of homomorphisms

$$M \xrightarrow{h} N_{n-1} \xrightarrow{g_{n-1}} \dots \xrightarrow{g_1} N_0 = N$$

with each  $N_i$  indecomposable, each  $g_i$  irreducible, and the composition  $g_1 \cdots g_{n-1} h$  non-trivial modulo  $\mathbf{x}^2$ . We wish to insert an indecomposable module  $N_n$  into the sequence, extending it by one step. There are two cases, according to whether or not  $N_{n-1}$  is free.

If  $N_{n-1}$  is not free, then there is an AR sequence  $0 \rightarrow \tau(N_{n-1}) \xrightarrow{i} E \xrightarrow{p} N_{n-1} \rightarrow 0$  ending in  $N_{n-1}$ . Since there is no path from  $[M]$  to  $[N]$  of length  $n - 1$ , we see that  $h$  is not an isomorphism, so is not a split surjection since  $M$  and  $N_{n-1}$  are both indecomposable. Therefore  $h$  factors through  $E$ , say

as  $M \xrightarrow{\alpha} E \xrightarrow{p} N_{n-1}$ . Write  $E$  as a direct sum of indecomposable MCM modules  $E = \bigoplus_{i=1}^r E_i$ , and decompose  $\alpha$  and  $q$  accordingly,  $M \xrightarrow{\alpha_i} E \xrightarrow{p_i} N_{n-1}$ . Each  $p_i$  is irreducible by Proposition 12.25, and there must exist at least one  $i$  such that  $g_1 \cdots g_{n-1} p_i \alpha_i$  is non-trivial modulo  $\mathfrak{x}^2$ . Set  $N_n = E_i$  and  $g_n = p_i$ , extending the sequence one step.

If  $N_{n-1}$  is free, then  $N_{n-1} \cong R$ , and the image of  $M$  is contained in  $\mathfrak{m}$  since  $h$  is not an isomorphism. Let  $0 \rightarrow Y \xrightarrow{i} X \xrightarrow{p} \mathfrak{m} \rightarrow 0$  be a minimal MCM approximation of  $\mathfrak{m}$ . (If  $\dim R \leq 1$ , we take  $X = \mathfrak{m}$  and  $Y = 0$ .) The homomorphism  $h: M \rightarrow \mathfrak{m}$  factors through  $X$  as  $M \xrightarrow{\alpha} X \xrightarrow{p} \mathfrak{m}$ . Decompose  $X = \bigoplus_{i=1}^r X_i$  where each  $X_i$  is indecomposable, and write  $p = \sum_{i=1}^r p_i$ , where  $p_i: X_i \rightarrow \mathfrak{m}$ . By Proposition 12.27, each composition  $X_i \xrightarrow{p_i} \mathfrak{m} \hookrightarrow R$  is an irreducible homomorphism, and again we may choose  $i$  so that the composition  $g_1 \cdots g_{n-1} p_i \alpha_i$  is non-trivial modulo  $\mathfrak{x}^2$ .  $\square$

**14.24 Lemma.** *Let  $\Gamma^\circ$  be a connected component of the AR quiver  $\Gamma$  of  $R$ , and assume that  $\ell(M/\mathfrak{x}^2 M) \leq m$  for every  $[M]$  in  $\Gamma^\circ$ . Let  $\varphi: M \rightarrow N$  be a homomorphism between indecomposable MCM  $R$ -modules which is non-trivial modulo  $\mathfrak{x}^2$ , and assume that either  $[M]$  or  $[N]$  is in  $\Gamma^\circ$ . Then there is a directed path of length  $< 2^m$  from  $[M]$  to  $[N]$  in  $\Gamma$  which is non-trivial modulo  $\mathfrak{x}^2$ . In particular, both  $[M]$  and  $[N]$  are in  $\Gamma^\circ$  if either one is.*

*Proof.* Assume that  $[N]$  is in  $\Gamma^\circ$ . If there is no directed path of length  $< 2^m$  from  $[M]$  to  $[N]$ , then by Lemma 14.23 there is a sequence of homomorphisms

$$M \xrightarrow{h} N_n \xrightarrow{g_n} N_{n-1} \xrightarrow{g_{n-1}} \cdots \xrightarrow{g_1} N_0 = N$$

with each  $N_i$  indecomposable, each  $g_i$  irreducible, and the composition

$g_1 \cdots g_{2^m} h$  non-trivial modulo  $\mathbf{x}^2$ . Since  $\Gamma^\circ$  is connected, each  $[N_i]$  is in  $\Gamma^\circ$ , so that  $\ell(N_i/\mathbf{x}^2 N_i) \leq m$  for each  $i$ . By the Harada-Sai Lemma 14.20,  $g_1 \cdots g_{2^m}$  is trivial modulo  $\mathbf{x}^2$ , a contradiction.

A symmetric argument using the other half of Lemma 14.23 takes care of the case where  $[M]$  is in  $\Gamma^\circ$ .  $\square$

We are now ready for the proof of Brauer-Thrall I in the complete case. Keep notation as in the statement of Theorem 14.22.

*Proof of Theorem 14.22.* We have  $e(M) \leq B$  for every  $[M]$  in  $\Gamma^\circ$ . Choose  $t$  large enough that  $\mathfrak{m}^t \subseteq (\mathbf{x}^2)$ , where  $\mathbf{x}$  is the faithful system of parameters guaranteed by Theorem 14.19. Then (see Appendix A)  $\ell(M/\mathbf{x}^2 M) \leq t^{\dim R} B$  for every  $[M]$  in  $\Gamma^\circ$ . Set  $m = t^{\dim R} B$ .

Let  $M$  be any indecomposable MCM module such that  $[M]$  is in  $\Gamma^\circ$ . By NAK, there is an element  $z \in M \setminus \mathbf{x}^2 M$ . Define  $\varphi: R \rightarrow M$  by  $\varphi(1) = z$ ; then  $\varphi$  is non-trivial modulo  $\mathbf{x}^2$ . By Lemma 14.24,  $[R]$  is in  $\Gamma^\circ$ , and is connected to  $[M]$  by a path of length  $< 2^m$  in  $\Gamma^\circ$ .

Now let  $[N]$  be arbitrary in  $\Gamma$ . The same argument shows that there is a homomorphism  $\psi: R \rightarrow N$  which is non-trivial modulo  $\mathbf{x}^2$ , whence  $[N]$  is in  $\Gamma^\circ$  as well, connected to  $[R]$  by a path of length  $< 2^m$ . Thus  $\Gamma = \Gamma^\circ$ , and since  $\Gamma$  is a locally finite group of finite diameter,  $\Gamma$  is finite.  $\square$

To complete the proof of Theorem 14.21, we need to know that for  $R$  an excellent isolated singularity, the hypotheses ascend to the completion  $\widehat{R}$ , and the conclusion descends back down to  $R$ . We have verified most of these details in previous chapters, and all that remains is to assemble the pieces.

*Proof of Theorem 14.21.* Let  $R$  be as in the statement of the theorem, so that  $R$  is excellent and has a perfect coefficient field. If  $R$  has finite CM type, then  $R$  has at most an isolated singularity by Theorem 7.12, and of course  $R$  has bounded CM type.

Suppose now that  $R$  has bounded CM type and at most an isolated singularity. Since  $R$  is excellent, both the Henselization  $R^h$  and the completion  $\widehat{R}$  have isolated singularities as well (this was verified in the course of the proof of Corollary 10.10). In particular,  $R^h$  is Gorenstein on the punctured spectrum, so by Proposition 10.6, every MCM  $R^h$ -module  $M$  is a direct summand of an extended MCM  $R$ -module  $N$ . Since  $R$  has bounded CM type, we can write  $N$  as a direct sum of MCM  $R$ -modules  $N_i$  of bounded multiplicity. Using KRS over  $R^h$ , we deduce that  $M$  is a direct summand of some  $N_i \otimes_R R^h$ , thereby getting a bound on the multiplicity of  $M$ . Thus  $R^h$  has bounded CM type as well.

Next we must verify that bounded CM type ascends from  $R^h$  to  $\widehat{R}$ . An arbitrary MCM  $\widehat{R}$ -module  $M$  is locally free on the punctured spectrum of  $\widehat{R}$ , since  $\widehat{R}$  has at most an isolated singularity. Thus by Elkik's Theorem 10.9,  $M$  is extended from the Henselization. It follows immediately that  $\widehat{R}$  has bounded CM type.

By Theorem 14.22,  $\widehat{R}$  has finite CM type. This descends to  $R$  by Theorem 10.1, completing the proof.  $\square$

One cannot completely remove the hypothesis of excellence in Theorem 14.21. For example, let  $S$  be any one-dimensional analytically ramified local domain. It is known [Mat73, pp. 138–139] that there is a one-dimensional local domain  $R$  between  $S$  and its quotient field such that

$e(R) = 2$  and  $\widehat{R}$  is not reduced. Then  $R$  has bounded but infinite CM type by Theorem 4.18, and of course  $R$  has an isolated singularity.

## §4 Brauer-Thrall II

Suppose  $(R, \mathfrak{m}, k)$  is a complete isolated singularity with algebraically closed residue field  $k$ . The second Brauer-Thrall conjecture, transplanted to the context of MCM modules, states that if  $R$  has infinite CM type then there is an infinite sequence of positive integers  $n_1 < n_2 < n_3 < \dots$  with the following property: for each  $i$  there are infinitely many non-isomorphic indecomposable MCM  $R$ -modules of multiplicity  $n_i$ .

In 1987 Dieterich [Die87] verified Brauer-Thrall II for hypersurfaces  $k[[x_0, \dots, x_d]]/(f)$  where  $\text{char}(k) \neq 2$ . Popescu and Roczen generalized Dieterich's results to excellent Henselian rings [PR90] and to characteristic two in [PR91].

In Chapter 4 we proved a very general version of Brauer-Thrall II for one-dimensional rings. Here we give a less computational proof (with mild restrictions). This proof rests on an inductive step, due to Smalø [Sma80], for concluding, from the existence of infinitely many indecomposable modules of a given multiplicity, infinitely many of a higher multiplicity.

Smalø's theorem also confirms Brauer-Thrall II for isolated singularities of uncountable CM type, as we point out at the end of the section. Smalø's result is quite general, and we feel it deserves to be better known.

We need two lemmas aimed at controlling the growth of multiplicity as one walks through an AR quiver. The first is a general fact about Betti

numbers [Avr98, Lemma 4.2.7].

**14.25 Lemma.** *Let  $(R, \mathfrak{m}, k)$  be a CM local ring of dimension  $d$  and multiplicity  $e$ , and let  $M$  be a finitely generated  $R$ -module. Then*

$$\mu_R(\operatorname{redsyz}_{n+1}^R(M)) \leq (e - 1)\mu_R(\operatorname{redsyz}_n^R(M))$$

for all  $n > d - \operatorname{depth} M$ .

*Proof.* We may replace  $M$  by  $\operatorname{redsyz}_{d-\operatorname{depth} M}^R(M)$  to assume that  $M$  is MCM. We may also assume that the residue field  $k$  is infinite, by passing if necessary to an elementary gonflement  $R' = R[t]_{\mathfrak{m}[t]}$ , which preserves the multiplicity of  $R$  and number of generators of syzygies of  $M$ . In this case (see Appendix A, §2), there exists an  $R$ -regular and  $M$ -regular sequence  $\mathbf{x} = x_1, \dots, x_d$  such that  $e(R) = e(R/(\mathbf{x})) = \ell(R/(\mathbf{x}))$ , and we have  $\mu_R(\operatorname{redsyz}_n^R(M)) = \mu_{R/(\mathbf{x})}(\operatorname{redsyz}_n^{R/(\mathbf{x})}(M \otimes_R R/(\mathbf{x})))$ . We are thus reduced to the case where  $R$  is Artinian of length  $e$ .

In a minimal free resolution  $F_\bullet$  of  $M$ , we have  $\operatorname{redsyz}_{n+1}^R(M) \subseteq \mathfrak{m}F_n$ , so that

$$(e - 1)\mu_R(\operatorname{redsyz}_n^R(M)) = \ell(\mathfrak{m}F_n) \geq \ell(\operatorname{redsyz}_{n+1}^R(M)) \geq \mu_R(\operatorname{redsyz}_{n+1}^R(M)),$$

for all  $n \geq 1$ . □

**14.26 Lemma.** *Let  $(R, \mathfrak{m})$  be a complete CM local ring with algebraically closed residue field, and assume that  $R$  has an isolated singularity. Then there exists a constant  $c = c(R)$  such that if  $X \rightarrow Y$  is an irreducible homomorphism of MCM  $R$ -modules, then  $e(X) \leq ce(Y)$  and  $e(Y) \leq ce(X)$ .*

*Proof.* Recall from Chapter 12 that the Auslander-Reiten translate  $\tau$  is given by  $\tau(M) = \text{Hom}_R(\text{redsyz}_d^R \text{Tr} M, \omega)$ , where  $\omega$  is the canonical module for  $R$ . We first claim that

$$(14.26.1) \quad e(\tau(M)) \leq e(e-1)^{d+1} e(M),$$

where  $e = e(R)$  is the multiplicity of  $R$ . To see this, it suffices to prove the inequality for  $e(\text{redsyz}_d^R(\text{Tr} M))$ , since dualizing into the canonical module preserves multiplicity. By Lemma 14.25, we have only to prove that  $e(\text{Tr} M) \leq e(e-1)e(M)$ . Let  $F_1 \rightarrow F_0 \rightarrow M \rightarrow 0$  be a minimal free presentation of  $M$ , so that  $F_0^* \rightarrow F_1^* \rightarrow \text{Tr} M \rightarrow 0$  is a free presentation of  $\text{Tr} M$ . Then

$$e(\text{Tr} M) \leq e(F_1^*) = e \mu_R(\text{redsyz}_1^R(M)) \leq e(e-1)\mu_R(M) \leq e(e-1)e(M),$$

finishing the claim.

Now to the proof of the lemma. We may assume that  $X$  and  $Y$  are indecomposable. First suppose that  $Y$  is not free. Then there is an AR sequence

$$0 \rightarrow \tau(Y) \rightarrow E \rightarrow Y \rightarrow 0$$

ending in  $Y$ , and  $X$  is a direct summand of  $E$  by Proposition 12.25. Then

$$\begin{aligned} e(E) &= e(\tau(Y)) + e(Y) \\ &\leq [e(e-1)^{d+1} + 1]e(Y) \end{aligned}$$

so  $e(X) \leq [e(e-1)^{d+1} + 1]e(Y)$ .

Now suppose that  $Y \cong R$  is free. Then  $X$  is a direct summand of the MCM approximation  $E$  of the maximal ideal  $\mathfrak{m}$  by Proposition 12.25, so  $e(X) \leq e(E)$  is bounded in terms of  $e(R)$ .

The other inequality is similar. □

**14.27 Theorem** (Smalø). *Let  $(R, \mathfrak{m})$  be a complete CM local ring with algebraically closed residue field, and assume that  $R$  has an isolated singularity. Assume that  $\{M_i \mid i \in I\}$  is an infinite family of pairwise non-isomorphic indecomposable MCM  $R$ -modules of multiplicity  $b$ . Then there exists an integer  $b' > b$ , a positive integer  $t$ , and a subset  $J \subseteq I$  with  $|J| = |I|$  such that there is a family  $\{N_j \mid j \in J\}$  of pairwise non-isomorphic indecomposable MCM  $R$ -modules of multiplicity  $b'$ . Furthermore there exist non-zero homomorphisms  $M_j \rightarrow N_j$ , each of which is a composition of  $t$  irreducible maps.*

*Proof.* Set  $s = 2^b - 1$ . First observe that since the AR quiver of  $R$  is locally finite, there are at most finitely many  $M_i$  such that there is a chain of strictly fewer than  $s$  irreducible maps starting at  $M_i$  and ending at the canonical module  $\omega$ . Deleting these indices  $i$ , we obtain  $J' \subseteq I$ .

Each  $M_i$  is MCM, so  $\text{Hom}_R(M_i, \omega)$  is non-zero for each remaining  $M_i$ . By NAK, there exists  $\varphi \in \text{Hom}_R(M_i, \omega)$  which is non-trivial modulo  $\mathfrak{x}^2$ . Hence by Lemma 14.23 there is a sequence of homomorphisms

$$M_i = N_{i,0} \xrightarrow{f_{i,1}} N_{i,1} \xrightarrow{f_{i,2}} \cdots \longrightarrow N_{i,s-1} \xrightarrow{f_{i,s}} N_{i,s} \xrightarrow{g} \omega$$

with each  $N_{i,j}$  indecomposable, each  $f_{i,j}$  irreducible, and the composition  $g f_{i,s} \cdots f_{i,1}$  non-trivial modulo  $\mathfrak{x}^2$ .

By the Harada-Sai Lemma 14.20, not all the  $N_{i,j}$  can have multiplicity less than or equal to  $b$ . So there exists  $J'' \subseteq J'$ , of the same cardinality, and  $t \leq s$  such that  $e(N_{i,t}) > b$  for all  $i$ .

Applying Lemma 14.26 to the irreducible maps connecting  $M_i$  to  $N_{i,t}$ , we find that

$$b < e(N_{i,t}) \leq c^t e(N_{i,0}) = c^t b$$

for some constant  $c$  depending only on  $R$ . There are thus only finitely many possibilities for  $e(N_{i,t})$  as  $i$  ranges over  $J''$ , and we take  $J''' \subseteq J''$  such that  $e(N_{i,t}) = b' > b$  for all  $i \in J'''$ .

There may be some repetitions among the isomorphism classes of the  $N_{i,t}$ . However, for any indecomposable MCM module  $N$ , there are only finitely many  $M$  with chains of irreducible maps of length  $t$  from  $M$  to  $N$ , so each isomorphism class of  $N_{i,t}$  occurs only finitely many times. Pruning away these repetitions, we finally obtain  $J = J'''' \subseteq I$  as desired.  $\square$

In Theorem 4.10 we proved a strong form of Brauer-Thrall II for the case of a one-dimensional analytically unramified local ring  $(R, \mathfrak{m}, k)$ . Here we indicate how one can use Smalø's theorem to give a much less computational proof of strongly unbounded CM type when  $R$  is complete and  $k$  is algebraically closed.

**14.28 Theorem.** *Let  $(R, \mathfrak{m}, k)$  be a complete CM local ring of dimension one with algebraically closed residue field  $k$ . Suppose that  $R$  does not satisfy the Drozd-Roïter conditions (DR) of Chapter 4. Then, for infinitely many positive integers  $n$ , there exist  $|k|$  pairwise non-isomorphic indecomposable MCM  $R$ -modules of multiplicity  $n$ .*  $\square$

*Proof.* It will suffice to show that  $R$  has infinitely many non-isomorphic faithful ideals, for then an easy argument such as in Exercise 4.31 produces infinitely many non-isomorphic ideals that are indecomposable as

$R$ -modules, and, consequently, infinitely many of fixed multiplicity. By Construction 4.1 it will suffice to produce an infinite family of pairwise non-isomorphic modules  $V_t \hookrightarrow \overline{R}/c$  over the Artinian pair  $R/c \hookrightarrow \overline{R}/c$ . We follow the argument in the proof of [Wie89, Proposition 4.2]. Using Lemmas 3.8 and 3.9 and Proposition 3.10, we can pass to the Artinian pair  $\mathbf{A} := k \hookrightarrow D$ , where either (i)  $\dim_k(D) \geq 4$  or (ii)  $D \cong k[x, y]/(x^2, xy, y^2)$ . It is easy to see that if  $U$  and  $V$  are distinct rings between  $k$  and  $D$  then the  $\mathbf{A}$ -modules  $U \hookrightarrow D$  and  $V \hookrightarrow D$  are non-isomorphic. Therefore we may assume that there are only finitely many intermediate rings. The usual proof of the primitive element theorem then provides an element  $\alpha \in D$  such that  $D = k[\alpha]$ . This rules out (ii), so we may assume that  $\dim_k(D) \geq 4$ .

For each  $t \in k$ , let  $I_t$  be the  $k$ -subspace of  $D$  spanned by 1 and  $\alpha + t\alpha^2$ . By Exercise 14.38, there are infinitely many non-isomorphic  $\mathbf{A}$ -modules  $I_t \hookrightarrow D$  as  $t$  varies over  $k$ .  $\square$

In higher dimensions, one cannot hope to prove the base case of Brauer-Thrall II by constructing an infinite family of MCM ideals. At least for hypersurfaces, there are lower bounds on the ranks of stable MCM modules (Corollary 14.30 below). These bounds depend on the following theorem of Bruns [Bru81, Corollary 2]:

**14.29 Theorem (Bruns).** *Let  $R$  be a commutative Noetherian ring and  $M$  a finitely generated  $R$ -module which is free of constant rank  $r$  at the associated primes of  $R$ . Let  $N$  be a second syzygy of  $M$ , and set  $s = \text{rank } N$ . If  $M$  is not free, then the codimension of the non-free locus of  $M$  is  $\leq r + s + 1$ .  $\square$*

**14.30 Corollary.** *Let  $(R, \mathfrak{m})$  be a hypersurface, and suppose that the singular locus of  $R$  is contained in a closed set of codimension  $c$ . Let  $M$  be a non-zero stable MCM module of constant rank  $r$  at the minimal primes of  $R$ . Then  $r \geq \frac{1}{2}(c - 1)$ .*

*Proof.* Since  $R$  is a hypersurface and  $M$  is stable MCM, Proposition 8.6 says that the second syzygy of  $M$  is isomorphic to  $M$ . Moreover, the non-free locus of  $M$  is contained in the singular locus of  $R$  by the Auslander-Buchsbaum formula. Therefore  $c$  is less than or equal to the codimension of the non-free locus of  $M$ . The inequality in Theorem 14.29 now give the inequality  $c \leq 2r + 1$ .  $\square$

**14.31 Corollary.** *Let  $(R, \mathfrak{m})$  be a hypersurface, and assume  $R$  is an isolated singularity of dimension  $d$ . Let  $M$  be a non-zero stable MCM module of constant rank  $r$  at the minimal primes of  $R$ . Then  $r \geq \frac{1}{2}(d - 1)$ .*  $\square$

This bound is probably much too low. In fact, Buchweitz, Greuel and Schreyer [BGS87] conjecture that  $r \geq 2^{d-2}$  for hypersurface isolated singularities. Still, the bound given in the corollary rules out MCM ideals once the dimension exceeds three.

Suppose, for example, that  $R = \mathbb{C}[[x_0, x_1, x_2, x_3, x_4]]/(x_0^4 + x_1^5 + x_2^2 + x_3^2 + x_4^2)$ . This has uncountable CM type, by the results of Chapters 9 and 13. Every MCM ideal of  $R$ , however, is principal, by Corollary 14.31. On the other hand, since  $R$  has uncountable CM type there must be *some* positive integer  $r$  for which there are uncountably many indecomposable MCM modules of rank  $r$ . Of course this works whenever we have uncountable CM type:

**14.32 Proposition.** *Let  $(R, \mathfrak{m}, k)$  be a CM local ring with uncountable CM type. Then Brauer-Thrall II holds for  $R$ .*

Using the structure theorem for hypersurfaces of countable CM type, we can recover Dieterich's theorem [Die87], as long as the ground field is uncountable:

**14.33 Theorem (Dieterich).** *Let  $(R, \mathfrak{m}, k)$  be a complete hypersurface which is an isolated singularity. Assume  $k$  is uncountable, algebraically closed, and of characteristic different from two. If  $R$  has infinite CM type, then Brauer-Thrall II holds for  $R$ .*

*Proof.* Since  $R$  is an isolated singularity, Theorem 13.16 ensures that  $R$  has uncountable CM type. □

## §5 Exercises

**14.34 Exercise.** Prove Lemma 14.13: For any ring  $\Gamma$  and any quotient ring  $\Lambda = \Gamma/I$ , the annihilator  $\text{Ann}_\Gamma I$  annihilates  $\text{Ext}_\Gamma^1(\Lambda, K)$  for every  $\Gamma$ -module  $K$ .

**14.35 Exercise.** Let  $R$  be a Noetherian ring and  $T$  a subring over which  $R$  is finitely generated as an algebra. Prove that  $J_T(R) \subseteq \mathfrak{S}_T(R)$ .

**14.36 Exercise.** Fill in the details of the proof of Theorem 14.19: show by induction on  $j$  that we may find regular local subrings  $T_1, \dots, T_j$  and elements  $x_i \in J_{T_i}(R)$  such that  $x_1, \dots, x_j$  is part of a system of parameters. For the inductive step, use prime avoidance.

**14.37 Exercise.** Suppose that  $\mathbf{x} = x_1, \dots, x_d$  is a faithful system of parameters in a local ring  $R$ . Prove that  $R$  has at most an isolated singularity.

**14.38 Exercise.** Let  $k$  be an infinite field and  $D$  a  $k$ -algebra with  $4 \leq d := \dim_k(D) < \infty$ . Assume there is an element  $\alpha \in D$  such that  $D = k[\alpha]$ . For  $t \in k$ , let  $I_t = k + k(\alpha + t\alpha^2)$ , and consider the  $(k \hookrightarrow D)$ -modules  $I_t \hookrightarrow D$ . For fixed  $t \in k$ , show that there are at most two elements  $u \in k$  for which  $I_u \hookrightarrow D$  and  $I_t \hookrightarrow D$  are isomorphic as  $(k \hookrightarrow D)$ -modules. (It is helpful to treat the cases  $d = 4$  and  $d > 4$  separately.)

## *Finite CM type in higher dimensions*

The results of Chapters 3, 4, and 7 give clear descriptions of the CM local rings of finite CM type in small dimension. For dimension greater than two, much less is known. Gorenstein rings of finite CM type are characterized by Theorem 9.15, but there are only two non-Gorenstein examples of dimension greater than two in the literature. In this chapter we describe these examples, and also present the theorem of Eisenbud and Herzog that these examples, together with those of the previous chapters, encompass all the *homogeneous* CM rings of finite CM type.

### §1 Two examples

We give in this section the two known examples of non-Gorenstein Cohen-Macaulay local rings of finite CM type in dimension at least 3. They are taken from [AR89]. We also quote two theorems from [AR89] to the effect that each example is the only one of its kind.

First we strengthen the Brauer-Thrall Theorem 14.22 slightly for non-Gorenstein rings.

Let  $(R, \mathfrak{m}, k)$  be a complete equicharacteristic CM local ring with algebraically closed residue field  $k$ , and assume that  $R$  has an isolated singularity. It follows from Theorem 14.22 that if  $\mathcal{C} = \{M_1, \dots, M_r\}$  is a finite set of indecomposable MCM  $R$ -modules which is closed under irreducible maps

(i.e. for an irreducible map  $X \rightarrow Y$  between indecomposable MCM modules, we have  $X \in \mathcal{C}$  if and only if  $Y \in \mathcal{C}$ ), then  $R$  has finite CM type and  $\mathcal{C}$  contains all the indecomposables. When  $R$  is not Gorenstein, a slightly weaker condition suffices. Say that a set  $\mathcal{C}$  of indecomposable MCM modules is *closed under AR sequences* if for each indecomposable non-free module  $M \in \mathcal{C}$ , and each indecomposable module  $N \in \mathcal{C}$  not isomorphic to the canonical module  $\omega$ , all indecomposable summands of the terms in the AR sequences  $0 \rightarrow \tau(M) \rightarrow E \rightarrow M \rightarrow 0$  and  $0 \rightarrow N \rightarrow E' \rightarrow \tau^{-1}(N) \rightarrow 0$  are in  $\mathcal{C}$ .

**15.1 Proposition.** *Let  $(R, \mathfrak{m}, k)$  be a complete equicharacteristic CM local ring with algebraically closed residue field  $k$  and with an isolated singularity. Assume that  $R$  is not Gorenstein. If  $\mathcal{C}$  is a set of indecomposable MCM  $R$ -modules which contains  $R$  and the canonical module  $\omega$ , and is closed under AR sequences, then  $\mathcal{C}$  is closed under irreducible homomorphisms. If in addition  $\mathcal{C}$  is finite, then  $R$  has finite CM type.*

*Proof.* The last sentence follows from the ones before by Theorem 14.22.

Let  $f: X \rightarrow Y$  be an irreducible homomorphism with  $X$  and  $Y$  indecomposable MCM  $R$ -modules. Assume that  $Y \in \mathcal{C}$ ; the other case is dual. We may assume that  $X \not\cong \omega$ . If  $Y \not\cong R$ , then there is an AR sequence ending in  $Y$ :  $0 \rightarrow \tau Y \rightarrow E \xrightarrow{p} Y \rightarrow 0$ . By Proposition 12.25,  $f$  is a component of  $p$ , so in particular  $X \mid E$ . Since  $\mathcal{C}$  is closed under AR sequences,  $X \in \mathcal{C}$ .

If  $Y \cong R$ , then  $Y \not\cong \omega$ . There is thus an AR sequence beginning in  $Y$ :  $0 \rightarrow Y \rightarrow E \rightarrow \tau^{-1}Y \rightarrow 0$ . By Exercise 15.8,  $f: X \rightarrow Y$  induces an irreducible homomorphism  $\tau^{-1}f: \tau^{-1}X \rightarrow \tau^{-1}Y$ . Since  $\tau^{-1}Y \not\cong R$ , the first case implies that  $\tau^{-1}X \in \mathcal{C}$ , whence  $X \in \mathcal{C}$  and we are done.  $\square$

**15.2 Example.** Let  $S = k[[x, y, z, u, v]]$  and  $R = S/(yv - zu, yu - xv, xz - y^2)$ , where  $k$  is an algebraically closed field of characteristic different from 2. Then  $R$  has finite CM type.

Define matrices over  $S$

$$\psi = \begin{bmatrix} yv - zu & yu - xv & xz - y^2 \end{bmatrix} \quad \text{and} \quad \varphi = \begin{bmatrix} x & y \\ y & z \\ u & v \end{bmatrix},$$

so that the entries of  $\psi$  are the  $2 \times 2$  minors of  $\varphi$ , and we have  $R = \text{cok } \psi$ . Then the  $S$ -free resolution of  $R$  is a Hilbert-Burch type resolution

$$0 \longrightarrow S^{(2)} \xrightarrow{\varphi} S^{(3)} \xrightarrow{\psi} S \longrightarrow R \longrightarrow 0.$$

In particular,  $R$  has depth 3. The sequence  $x, v, z - u$  is a system of parameters, so  $R$  is CM. Since the characteristic of  $k$  is not 2, the Jacobian criterion (Theorem 14.18) implies that  $R$  is an isolated singularity, whence in particular a normal domain.

The canonical module  $\omega = \text{Ext}_S^2(R, S)$  is presented over  $R$  by the transpose of the matrix  $\varphi$ . This is easily checked to be isomorphic to the ideal  $(u, v)$ . (The natural map from  $\omega$  to  $(-v, u)$  is surjective and has kernel of rank zero, so is an isomorphism.)

Set further  $I = (x, y, u)$  and  $J = (x, y, z)$ . Each is an ideal of height one in  $R$ , with quotient a power series ring of dimension 2, so is a MCM  $R$ -module. We also have  $I \cong \text{redsyz}_1^R(\omega)$  and  $J \cong I^\vee = \text{Hom}_R(I, \omega)$ . By Exercise 15.10, we have  $I \cong \omega^*$  as well.

Let us compute the AR translates  $\tau(-) = \text{redsyz}_3^R(\text{Tr}(-))^\vee \cong (\text{redsyz}_1^R(-^*))^\vee$ .

We have

$$\tau(I) = \text{redsyz}_1^R(I^*)^\vee \cong \text{redsyz}_1^R(\omega)^\vee \cong I^\vee = J.$$

Similarly

$$\tau(\omega) = \text{redsyz}_1^R(\omega^*)^\vee \cong \text{redsyz}_1^R(I)^\vee.$$

Set  $M = \text{redsyz}_1^R(I)^\vee$ , a MCM  $R$ -module of rank 2 which is indecomposable by Proposition 12.12, so that  $\tau(\omega) = M$ . To finish the AR translates, note that  $J^*$  is isomorphic to the ideal  $(x, u^2)$  and  $\text{redsyz}_1^R((x, u^2)) \cong J$ , whence  $\tau(J) = J^\vee \cong I$ . Finally  $\tau(M) = (I^*)^\vee = R$ .

The syzygy module  $M^\vee = \text{redsyz}_1^R((x, y, u))$  is generated by the following six elements of  $R^{(3)}$ : the Koszul relations

$$z_1 = \begin{pmatrix} 0 \\ -u \\ y \end{pmatrix}, \quad z_2 = \begin{pmatrix} -u \\ 0 \\ x \end{pmatrix}, \quad z_3 = \begin{pmatrix} -y \\ x \\ 0 \end{pmatrix},$$

and the three additional relations

$$z_4 = \begin{pmatrix} 0 \\ -v \\ z \end{pmatrix}, \quad z_5 = \begin{pmatrix} -v \\ 0 \\ y \end{pmatrix}, \quad z_6 = \begin{pmatrix} -z \\ y \\ 0 \end{pmatrix}.$$

Define homomorphisms  $f: \omega \rightarrow M^\vee$ ,  $g: \omega \rightarrow M^\vee$ , and  $h: I \rightarrow M^\vee$  by

$$f(u) = z_1, \quad f(v) = z_4,$$

$$g(u) = z_2, \quad g(v) = z_5,$$

$$h(x) = z_3, \quad h(y) = z_6, \quad h(u) = \begin{pmatrix} -v & u & 0 \end{pmatrix}^T$$

One checks easily that  $f$ ,  $g$ , and  $h$  are well-defined, and that the sum  $(f, g, h): \omega^{(2)} \oplus I \rightarrow M^\vee$  is surjective. The kernel has rank one, and the class of the kernel in the divisor class group  $\text{Cl}(R)$  is equal to  $[R]$ , so is isomorphic to  $R$ . Thus we have a non-split short exact sequence

$$(15.2.1) \quad 0 \rightarrow R \rightarrow \omega^{(2)} \oplus I \rightarrow M^\vee \rightarrow 0.$$

Dualizing gives another non-split short exact sequence

$$(15.2.2) \quad 0 \longrightarrow M \longrightarrow R^{(2)} \oplus J \longrightarrow \omega \longrightarrow 0.$$

To show that these are both AR sequences, it suffices to prove that the stable endomorphism ring  $\underline{\text{End}}_R(\omega)$  is isomorphic to  $k$ . Indeed, in that case Proposition 12.16 reads

$$\text{Ext}_R^1(\omega, \tau(\omega)) \cong \text{Hom}_R(\underline{\text{End}}_R(\omega), E_R(k)) = k$$

so that any non-split extension in  $\text{Ext}_R^1(\omega, M)$  represents the AR sequence.

Since  $\omega I' = (x, y, z, u, v)$  for  $I' = (\frac{x}{u} \frac{y}{u}, 1) \cong I$ , Exercise 15.9 implies that multiplication by any  $r \in (x, y, z, u, v)$  factors through a free module. Thus  $\underline{\text{End}}_R(\omega) = k$ , and both (15.2.1) and (15.2.2) are AR sequences.

For the AR sequence ending in  $J$ , note that we already have an arrow  $M \longrightarrow J$  in the AR quiver. The AR sequence ending in  $J$  has rank-one modules on both ends, so the middle term has rank two. The middle term is thus isomorphic to  $M$ , and we have the AR sequence

$$0 \longrightarrow I \longrightarrow M \longrightarrow J \longrightarrow 0.$$

We also have an arrow  $I \longrightarrow M^\vee$ , so we must have  $M \cong M^\vee$ . Finally, the AR quiver is already known to contain arrows  $J \longrightarrow \omega$  and  $R \longrightarrow I$ , so the AR sequence ending in  $I$  is

$$0 \longrightarrow J \longrightarrow R \oplus \omega \longrightarrow I \longrightarrow 0.$$

The set  $\{R, \omega, I, J, M\}$  is thus closed under AR sequences, so that  $R$  has finite CM type by Proposition 15.1, and the AR quiver looks like the one

below.

The ring of Example 15.2 is an example of a *scroll*. Let  $(m_1, \dots, m_r)$  be positive integers with  $m_1 \geq m_2 \geq \dots \geq m_r$ , and consider a matrix of indeterminates

$$X = \left[ \begin{array}{ccc|ccc} x_{1,0} & \cdots & x_{1,m_1-1} & & & x_{r,0} & \cdots & x_{r,m_r-1} \\ x_{1,1} & \cdots & x_{1,m_1} & \cdots & & x_{r,1} & \cdots & x_{r,m_r} \end{array} \right]$$

over an infinite field  $k$ . The quotient ring  $R = k[[x_{ij}]]/I_2(X)$  by the ideal of  $2 \times 2$  minors of  $X$  is called a (complete) *scroll of type*  $(m_1, \dots, m_r)$ . Replacing the power series ring  $k[[x_{ij}]]$  by the polynomial ring  $k[x_{ij}]$  gives the *graded scrolls*. In either case,  $R$  is a CM normal domain of dimension  $r + 1$  and has an isolated singularity.

If  $r = 1$ , then the complete scroll  $R$  is isomorphic to the two-dimensional invariant ring  $k[[u^m, u^{m-1}v, \dots, v^m]]$ , so has finite CM type by Theorem 6.3. If  $R$  has type  $(1, 1)$ , then  $R \cong k[[x, y, z, w]]/(xy - zw)$  is a three-dimensional  $(A_1)$  hypersurface singularity, so again has finite CM type. The ring of Example 15.2 is of type  $(2, 1)$ . These are the only examples with finite CM type:

**15.3 Theorem** (Auslander-Reiten). *Let  $R$  be a complete or graded scroll of type different from  $(m)$ ,  $(1, 1)$ , and  $(2, 1)$ . Then  $R$  has infinite CM type.*

Auslander and Reiten prove Theorem 15.3 by constructing an infinite family of rank-two graded MCM modules, up to shift, over the graded scrolls  $k[x_{ij}]/I_2(X)$ . For example, assume that  $R$  is a graded scroll of type  $(n, 1)$ , with  $n \geq 3$ . Then  $R$  is the quotient of  $k[x_0, \dots, x_n, u, v]$  by the  $2 \times 2$  minors of the matrix

$$\begin{pmatrix} x_0 & \cdots & x_{n-1} & u \\ x_1 & \cdots & x_n & v \end{pmatrix}$$

so is a three-dimensional normal domain. Set  $A = (x_0^2, x_0x_1, \dots, x_0x_n)$  and  $B = (x_0^2, x_0x_1, \dots, x_0x_{n-1}, x_0u)$ . Then both  $A$  and  $B$  are indecomposable MCM  $R$ -modules of rank one. For  $\lambda \in k$ , let  $M_\lambda$  be the submodule of  $R^{(2)}$  generated by the vectors  $a_j = (x_0x_{j-1}, 0)$  for  $1 \leq j \leq n$ ,  $a_{n+1} = (x_0u, 0)$ ,  $a_j = (0, x_0x_{j-n-2})$  for  $n+2 \leq j \leq 2n$ ,  $a_{2n+1} = (x_0u, x_0x_{n-1})$ , and  $a_{2n+2} = (x_1u + \lambda x_0v, x_0x_n)$ . Then we have a natural inclusion  $B \xrightarrow{\beta} M_\lambda$  and a surjection  $M_\lambda \xrightarrow{\alpha} A$ .

Auslander and Reiten show that for each  $\lambda$  the sequence  $0 \rightarrow B \xrightarrow{\beta} M_\lambda \xrightarrow{\alpha} A \rightarrow 0$  is exact, so that  $M_\lambda$  is MCM. Furthermore an isomorphism  $f: M_\lambda \rightarrow M_\mu$  induces an isomorphism between the corresponding extensions, which forces  $\lambda = \mu$ . The modules  $\{M_\lambda\}_{\lambda \in k}$  thus form an infinite family of rank-two MCM modules.

The case of type  $(m_1, m_2, \dots, m_r)$  with  $m_2 + \dots + m_r \geq 2$  is handled similarly.

Here is the other example of this section.

**15.4 Example.** Let  $R$  be the invariant ring of Example 5.24, so that  $k$  is a field of characteristic different from 2,  $S = k[[x, y, z]]$ ,  $G$  is the cyclic group of order 2 with the generator acting on  $V = kx \oplus ky \oplus kz$  by negating each variable, and  $R = S^G = k[[x^2, xy, xz, y^2, yz, z^2]]$ . Then  $R$  has finite CM type.

Let  $k$  denote the trivial representation of  $G$ , and  $k_-$  the other irreducible representation. Note that  $V \cong k_-^{(3)}$ . The Koszul complex

$$0 \longrightarrow S \otimes_k \bigwedge^3 V \longrightarrow S \otimes_k \bigwedge^2 V \longrightarrow S \otimes_k V \longrightarrow S \longrightarrow k \longrightarrow 0$$

resolves  $k$  both over  $S$  and over the skew group ring  $S\#G$ . Replacing  $V$  by  $k_-^{(3)}$  and writing  $S_- = S \otimes_k k_-$ , we get

$$(15.4.1) \quad 0 \longrightarrow S_- \longrightarrow S^{(3)} \longrightarrow S_-^{(3)} \longrightarrow S \longrightarrow k \longrightarrow 0.$$

Tensor with  $k_-$  to obtain an exact sequence

$$(15.4.2) \quad 0 \longrightarrow S \longrightarrow S_-^{(3)} \longrightarrow S^{(3)} \longrightarrow S_- \longrightarrow k_- \longrightarrow 0.$$

As in Example 5.24, we find that the fixed submodule  $S_-^G$  is the  $R$ -submodule of  $S$  generated by  $(x, y, z)$ . In particular, we have  $S \cong S^G \oplus S_-^G$  as  $R$ -modules. Since  $S$  is Gorenstein, we must have  $\text{Hom}_R(S, \omega) \cong S$ , where  $\omega$  is the canonical module for  $R$ . In particular  $R \oplus S_-^G \cong \omega \oplus (S_-^G)^\vee$ . As  $R$  is not Gorenstein, this implies that  $\omega \cong S_-^G$ .

Applying  $(-)^G$  to the resolution of  $k_-$  gives an exact sequence of  $R$ -modules

$$0 \longrightarrow R \longrightarrow \omega^{(3)} \longrightarrow R^{(3)} \longrightarrow \omega \longrightarrow 0.$$

Set  $M = \text{redsyz}_1^R(\omega)$ , the kernel in the middle of this sequence, so that we have two short exact sequences

$$\begin{aligned} 0 \longrightarrow R \longrightarrow \omega^{(3)} \longrightarrow M \longrightarrow 0, \\ 0 \longrightarrow M \longrightarrow R^{(3)} \longrightarrow \omega \longrightarrow 0. \end{aligned}$$

By the symmetry of the Koszul complex, the canonical dual of the first sequence is isomorphic to the second, so that  $M^\vee \cong M$ . Furthermore the square of the fractional ideal  $\omega = (x, y, z)R$  is isomorphic to the maximal ideal of  $R$ , so that  $\omega^* = \omega$ . These allow us to compute the AR translates

$$\tau(\omega) = (\text{redsyz}_1^R(\omega^*))^\vee \cong M^\vee \cong M$$

and

$$\tau(M) = (\text{redsyz}_1^R(M^*))^\vee \cong \omega^\vee = R.$$

As in the previous example, the fact that  $\omega^2 = (x^2, xy, xz, y^2, yz, z^2)$  is the maximal ideal of  $R$  implies that  $\underline{\text{End}}_R(\omega) \cong k$ , so that  $\text{Ext}_R^1(\omega, M)$  is one-dimensional and

$$0 \longrightarrow M \longrightarrow R^{(3)} \longrightarrow \omega \longrightarrow 0$$

is the AR sequence for  $\omega$ . Dualizing gives

$$0 \longrightarrow R \longrightarrow \omega^{(3)} \longrightarrow M \longrightarrow 0,$$

the AR sequence for  $M$ .

The set of MCM modules  $\{R, \omega, M\}$  is thus closed under AR sequences, so that  $R$  has finite CM type by Proposition 15.1, and the AR quiver is

below.

As with the earlier example, the ring of Example 15.4 is the only one of its kind with finite CM type. The proof is more involved than in the earlier case; see [AR89].

**15.5 Theorem** (Auslander-Reiten). *Let  $S = k[[x_1, \dots, x_n]]$ , where  $k$  is an algebraically closed field and  $n \geq 3$ . Let  $G$  be a finite non-trivial group acting faithfully on  $S$ , such that  $|G|$  is invertible in  $k$ . Then the fixed ring  $R = S^G$  is of finite CM type if and only if  $n = 3$  and  $G$  is the group of order two, where the generator sends each variable to its negative.*

## §2 Classification for homogeneous CM rings

Together with the results of previous chapters, the examples of the previous section exhaust the known CM complete local rings of finite CM type. There is no complete classification known. For homogeneous CM rings, however, there is such a classification, due to [EH88].

Let  $k$  be an algebraically closed field of characteristic zero, and let  $R = \bigoplus_{n=0}^{\infty} R_n$  be a positively graded  $k$ -algebra, generated in degree one and with  $R_0 = k$ . We call such an  $R$  a *homogeneous ring*. We further say that a CM homogeneous ring  $R$  has *finite CM type* if, up to isomorphism and shifts of the grading, there are only finitely many MCM  $R$ -modules.

**15.6 Theorem** (Eisenbud-Herzog). *Let  $R$  be a CM homogeneous ring. Then  $R$  has finite CM type if and only if  $R$  is isomorphic to one of the rings in the following list.*

- (i)  $k[x_0, \dots, x_n]$  for some  $n \geq 0$ ;
- (ii)  $k[x_0, \dots, x_n]/(x_0^2 + \dots + x_n^2)$  for some  $n \geq 0$ ;
- (iii)  $k[x]/(x^m)$  for some  $m \geq 1$ ;
- (iv)  $k[x, y]/(xy(x + y))$ , a graded  $(D_4)$  hypersurface singularity;
- (v)  $k[x, y, z]/(xy, yz, xz)$ ;
- (vi)  $k[x_0, \dots, x_m]/I_2 \begin{bmatrix} x_0 & & & \\ & \ddots & & \\ & & x_{m-1} & \\ & & & x_m \end{bmatrix}$ , a graded scroll of type  $(m)$  for some  $m \geq 1$ ;
- (vii)  $k[x, y, z, u, v]/I_2 \begin{bmatrix} x & y & u \\ y & z & v \end{bmatrix}$ , a graded scroll of type  $(2, 1)$ ; and
- (viii)  $k[x, y, z, u, v, w]/I_2(A)$ , where  $A$  is the generic symmetric  $3 \times 3$  matrix

$$A = \begin{bmatrix} x & y & z \\ y & u & v \\ z & v & w \end{bmatrix}.$$

The rings in (vii) and (viii) are homogeneous versions of the rings in Examples 15.2 and 15.4. In particular

$$k[x, y, z, u, v, w]/I_2(A) \cong k[x^2, xy, xz, y^2, yz, z^2]$$

as non-homogeneous rings, though the ring on the right is not generated in degree one.

The classification follows from verifying Conjecture 7.21 for CM homogeneous domains:

**15.7 Theorem.** *Let  $R$  be a CM homogeneous domain of finite CM type. Then for any maximal regular sequence  $\mathbf{x}$  of elements of degree 1 in  $R$ , the quotient  $R' = R/(x)$  satisfies  $\dim_k R'_n \leq 1$  for all  $n \geq 2$ . In particular, if  $R$  is not Gorenstein then  $R$  has minimal multiplicity, i.e.*

$$e(R) = \mu_R(\mathfrak{m}) - \dim R + 1,$$

where  $\mathfrak{m} = \bigoplus_{n=1}^{\infty} R_n$  is the irrelevant maximal ideal of  $R$ .

Artinian homogeneous rings satisfying the condition  $\dim_k R'_n \leq 1$  for all  $n \geq 2$  are called *stretched* [Sal79]. Equivalently,  $R_{e-t} \neq 0$ , where  $e = e(R)$  is the multiplicity and  $t = \dim_k R_1$  is the embedding dimension of  $R$ .

*Proof of Theorem 15.6, assuming Theorem 15.7.* We may assume that  $R$  is not the polynomial ring. If  $R$  has dimension zero, then by Theorem 3.2 it is a principal ideal ring, so isomorphic to  $k[x]/(x^m)$  for some  $m \geq 1$ . If  $\dim R = 1$ , then by the graded version of Theorem 4.13  $R$  birationally dominates an ADE hypersurface singularity; the only graded rings among these are (ii) with  $n = 1$ , (iv), and (v).

Now assume that  $R$  has dimension at least 2. If  $R$  is Gorenstein, then by Theorem 9.16 it is an ADE hypersurface ring of multiplicity 2. Since  $R$  is homogeneous, this implies that  $R$  is the quadric hypersurface of (ii). Thus we may assume that  $R$  is not Gorenstein.

By Theorem 7.12,  $R$  is an isolated singularity. In particular, by Serre's criterion (Proposition A.8)  $R$  is a normal domain and has minimal multi-

plicity by Theorem 15.7. The homogeneous domains of minimal multiplicity are classified by the Del Pezzo-Bertini Theorem (see [EH87]). The ones with isolated singularities are

- (a) quadric hypersurface rings  $k[x_0, \dots, x_n]/(x_0^2 + \dots + x_n^2)$ ;
- (b) graded scrolls of arbitrary type  $(m_1, \dots, m_r)$ ; and
- (c) the ring of (viii).

Each ring in the first and third classes has finite CM type, while the only graded scrolls of finite CM type are those of type  $(m)$ ,  $(1, 1)$  (also a quadric hypersurface), and  $(2, 1)$  by Theorem 15.3.  $\square$

We sketch the proof that CM homogeneous rings of finite CM type are stretched. Let  $\mathbf{x} = x_1, \dots, x_d$  be a maximal regular sequence of elements of degree one in  $R$ , set  $R' = R/(\mathbf{x})$ , and assume that  $\dim_k R'_c \geq 2$  for some  $c \geq 2$ . For each  $u \in R'_c$ , let  $L_u = R'/(u)$ , and set  $M_u = \text{redsyz}_d^R(L_u)$ . Then each  $M_u$  is a graded MCM  $R$ -module. Eisenbud and Harris show:

- (a) there is an upper bound on the ranks of the  $M_u$ ;
- (b) each  $M_u$  has a unique (up to scalar multiple) generator  $f_u$  of degree  $d$ , and all other generators have degree  $> d$ ; and
- (c) if we denote by  $\overline{f_u}$  the image of  $f_u$  in  $M_u/\mathbf{x}M_u$ , then  $\text{Ann}_R(\overline{f_u}) = \text{Ann}_R(L_u)$ .

See the Exercises for proofs of these assertions. Assuming them, we can show that  $R$  is of infinite CM type. Indeed, if  $M_u \cong M_{u'}$  for  $u, u' \in R'_c$ , then

$M_u/\mathfrak{x}M_u \cong M_{u'}/\mathfrak{x}M_{u'}$ , via an isomorphism taking  $R\overline{f_u}$  to  $R\overline{f_{u'}}$ . It follows that the annihilators of  $L_u$  and  $L_{u'}$  are equal, and in particular  $(u) = (u')$  as ideals of  $R'$ . But since  $\dim_k R'_c \geq 2$ , there are infinitely many ideals of the form  $(u)$  for  $u \in R'_c$ . The bound on the ranks of the  $M_u$  thus implies that  $R$  has infinite CM type.

### §3 Exercises

**15.8 Exercise.** In the notation of Proposition 15.1, let  $0 \rightarrow N \rightarrow E \rightarrow \tau^{-1}N \rightarrow 0$  be an AR sequence and  $f: N \rightarrow Z$  a homomorphism between indecomposable MCM modules with  $Z \not\cong \omega$ . Prove that there is an induced homomorphism  $\tau^{-1}f: \tau^{-1}N \rightarrow \tau^{-1}Z$ , and that  $\tau^{-1}f$  is irreducible if  $f$  is.

**15.9 Exercise.** Let  $R$  be a Noetherian domain and  $I$  an ideal of  $R$ . Assume that there is a fractional ideal  $J$  of  $R$  such that  $IJ \subseteq R$ . Show that multiplication by an element  $r \in IJ$ , as a homomorphism  $I \rightarrow I$ , factors through a free  $R$ -module.

**15.10 Exercise.** Let  $L = (\alpha, b)$  be a two-generated ideal of a commutative ring  $R$  and let  $L^{-1} = \{\alpha \in K \mid \alpha L \subseteq R\}$ . Prove that there is a short exact sequence  $0 \rightarrow L^{-1} \xrightarrow{\begin{bmatrix} b \\ -\alpha \end{bmatrix}} R^2 \xrightarrow{[\alpha \ b]} L \rightarrow 0$ , so that  $L^{-1}$  is isomorphic to  $\text{syz}_1^R(L)$ . If  $L$  contains a non-zero-divisor, then  $L^{-1} \cong L^*$ .

**15.11 Exercise.** In the setup of the proof of Theorem 15.7, prove item (a), that the ranks of the modules  $M_u$  are bounded, by showing that the lengths of  $L_u$  are bounded and that  $\text{rank}(\text{redsyz}_R^d(L)) \leq \ell(L)\text{rank}(\text{redsyz}_d^R(k))$  for a module  $L$  of finite length.

**15.12 Exercise.** Prove (b) from the proof of Theorem 15.7 by constructing a comparison map between the  $R$ -free resolution  $F_\bullet$  of  $L_u$  and the Koszul complex  $K_\bullet$  on the regular sequence  $\mathbf{x}$ . Show by induction on  $i$  that the induced maps  $K_i/\mathfrak{m}_R K_i \rightarrow F_i/\mathfrak{m}_R F_i$  are all injective, so that  $K_\bullet$  is a direct summand of  $F_\bullet$ . Finally, show that the minimal generators of the quotient  $F_i/K_i$  are all in degrees  $> i$ .

**15.13 Exercise.** Continuing the notation of Exercise 15.12, prove that the kernel of the map  $M_u/\mathbf{x}M_u \rightarrow F_{d-1}/\mathbf{x}F_{d-1}$  is isomorphic to the  $d^{\text{th}}$  Koszul homology of  $\mathbf{x}$  on  $L_u$ , which is  $L_u$ . Conclude that the generator  $\overline{f_u}$  of  $K_d/\mathbf{x}K_d$  has annihilator equal to that of  $L_u$ .

## *Bounded type*

In this chapter we classify the complete equicharacteristic hypersurface rings of bounded CM type with residue field of characteristic not equal to 2. It is an astounding coincidence that the answer turns out to be precisely the same as in Chapter 13: The hypersurface rings of bounded but infinite type are the  $(A_\infty)$  and  $(D_\infty)$  hypersurface singularities in all positive dimensions. Note that the families of ideals showing (countable) non-simplicity in Lemma 9.3 for certain classes of hypersurface rings do not give rise to indecomposable modules of large rank; thus there does not seem to be a way to use the results of Chapter 13 to demonstrate unbounded CM type directly.

We also classify the one-dimensional complete CM local rings containing an infinite field and having bounded CM type. There is only one additional isomorphism type, which we have seen already in Example 13.23. The explicit classification, together with the results of Chapter 2, allows us to show that bounded type descends from the completion in dimension one.

### **§1 Hypersurface rings**

To classify the complete hypersurface rings of bounded CM type, we must use Knörrer's results from Chapter 8 to reduce the problem to the case of dimension one. It will be more convenient in what follows to find bounds on the minimal number of generators of MCM modules; luckily, this is the same as bounding their multiplicity. We leave the proof of this fact as an

exercise (Exercise 16.13).

**16.1 Lemma.** *Let  $A$  be a local ring. The multiplicities of indecomposable MCM  $A$ -modules are bounded if and only if their minimal numbers of generators are bounded.*

**16.2 Proposition.** *Let  $R = S/(f)$  be a complete equicharacteristic hypersurface singularity, where  $S = k[[x_0, \dots, x_d]]$  and  $f$  is a non-zero non-unit of  $S$ .*

- (i) *If  $R^\sharp$  has bounded CM type, then  $R$  has bounded CM type.*
- (ii) *If the characteristic of  $k$  is not 2, then the converse holds as well. More precisely, if  $\mu_R(M) \leq B$  for each indecomposable MCM  $R$ -module, then  $\mu_{R^\sharp}(N) \leq 2B$  for each indecomposable MCM  $R^\sharp$ -module  $N$ .*

*Proof.* Assume that  $R^\sharp$  has bounded CM type, and let  $B$  bound the minimal number of generators of MCM  $R^\sharp$ -modules. Let  $M$  be an indecomposable non-free MCM  $R$ -module. Then by Proposition 8.15  $M^{\sharp b} \cong M \oplus \text{syz}_1^R(M)$ , so  $M$  is a direct summand of  $M^{\sharp b}$ . Decompose  $M^{\sharp b}$  into indecomposable MCM  $R^\sharp$ -modules,  $M^{\sharp b} \cong N_1 \oplus \dots \oplus N_t$ . Then  $M^{\sharp b} \cong N_1^b \oplus \dots \oplus N_t^b$ , and by KRS  $M$  is a direct summand of some  $N_j^b$ . Since  $\mu_R(N_j^b) = \mu_{R^\sharp}(N_j)$  for each  $j$ , the result follows.

For the converse, assume  $\mu_R(M) \leq B$  for every indecomposable MCM  $R$ -module  $M$ , and let  $N$  be an indecomposable non-free MCM  $R^\sharp$ -module. By Proposition 8.17,  $N^{\sharp b} \cong N \oplus \text{syz}_1^{R^\sharp}(N)$ . Decompose  $N^b$  into indecomposable MCM  $R$ -modules,  $N^b \cong M_1 \oplus \dots \oplus M_s$ . Then  $N^{\sharp b} \cong M_1^\sharp \oplus \dots \oplus M_s^\sharp$ . By KRS again,  $N$  is a direct summand of some  $M_j^\sharp$ . It will suffice to show that  $\mu_{R^\sharp}(M_j^\sharp) \leq 2B$  for each  $j$ .

If  $M_j$  is not free, we have  $\mu_{R^\sharp}(M_j^\sharp) = \mu_R(M_j^{\sharp b}) = \mu_R(M_j) + \mu_R(\text{syz}_1^R(M))$  by Proposition 8.15. But since  $M_j$  is a MCM  $R$ -module, all of its Betti numbers are equal to  $\mu_R(M_j)$  by Proposition 8.6. Thus  $\mu_R(M_j^{\sharp b}) = 2\mu_R(M_j) \leq 2B$ . If, on the other hand,  $M_j = R$ , then  $M_j^\sharp \cong R^\sharp$ , and so  $\mu_{R^\sharp}(M_j^\sharp) = 1$ .  $\square$

Our next concern is to show that a hypersurface ring of bounded representation type has multiplicity at most two, as long as the dimension is greater than one. This is a corollary of the following result of Kawasaki [Kaw96, Theorem 4.1], due originally in the graded case to Herzog and Sanders [HS88]. (A similar result was obtained by Dieterich [Die87] using a theorem on the structure of the AR quiver of a complete isolated hypersurface singularity.) Recall that an *abstract hypersurface ring* is a Noetherian local ring  $(A, \mathfrak{m})$  such that the  $\mathfrak{m}$ -adic completion  $\widehat{A}$  is isomorphic to  $B/(f)$  for some regular local ring  $B$  and non-unit  $f$ .

**16.3 Theorem.** *Let  $(A, \mathfrak{m})$  be an abstract hypersurface ring of dimension  $d$ . Assume that the multiplicity  $e = e(A)$  is greater than 2. Then for each  $n > e$ , the module  $\text{syz}_{d+1}^A(A/\mathfrak{m}^n)$  is indecomposable and*

$$\mu_R\left(\text{syz}_{d+1}^A(A/\mathfrak{m}^n)\right) \geq \binom{d+n-1}{d-1}.$$

We omit the proof. Putting Kawasaki's theorem together with Herzog's Theorem 9.15, we have the following result.

**16.4 Proposition.** *Let  $(R, \mathfrak{m}, k)$  be a Gorenstein local ring of bounded CM type. Assume  $\dim R \geq 2$ . Then  $R$  is an abstract hypersurface ring of multiplicity at most 2.*

When the hypersurface ring in Proposition 16.4 is complete and contains an algebraically closed field of characteristic other than 2, we can show by the same arguments as in Chapter 9 that it is an iterated double branched cover of a one-dimensional hypersurface ring of bounded type.

**16.5 Theorem.** *Let  $k$  be an algebraically closed field of characteristic not equal to 2, and let  $R = k[[x_0, \dots, x_d]]/(f)$ , where  $f$  is a non-zero non-unit of the formal power series ring and  $d \geq 2$ . Then  $R$  has bounded CM type if and only if  $R \cong k[[x, \dots, x_d]]/(g + x_2^2 + \dots + x_d^2)$  for some  $g \in k[[x_0, x_1]]$  such that  $k[[x_0, x_1]]/(g)$  has bounded CM type.*

Actually, the arguments above do not apply to rings like  $k[[x_0, \dots, x_d]]/(x_d^2)$ , since they tacitly assume that  $g \neq 0$ . Indeed, these rings do not have finite or bounded CM type. Here is a proof of a more general result.

**16.6 Proposition.** *Let  $(S, \mathfrak{n}, k)$  be a CM local ring of dimension at least two, and let  $z$  be an indeterminate. Set  $R = S[z]/(z^2)$ . Then  $R$  has unbounded CM type.*

*Proof.* We will show that for every  $n \geq 2$  there is an indecomposable MCM  $R$ -module of rank  $2n$ . In fact, the proof is essentially identical to that of Theorem 3.2.

Fix  $n \geq 2$ , and let  $W$  be a free  $S$ -module of rank  $2n$ . Let  $I$  be the  $n \times n$  identity matrix and  $H$  the  $n \times n$  nilpotent Jordan block with 1 on the superdiagonal and 0 elsewhere. Let  $\{x, y\}$  be part of a minimal generating set for the maximal ideal  $\mathfrak{n}$  of  $S$ , and put  $\Psi = yI + xH$ . Finally, put  $\Phi = \begin{bmatrix} 0 & \Psi \\ 0 & 0 \end{bmatrix}$ . Noting that  $\Phi^2 = 0$ , we make  $W$  into an  $R$ -module by letting  $z$  act as

$\Phi: W \rightarrow W$ . Then  $W$  is a MCM  $R$ -module, and one shows as in the proof of Theorem 3.2 that  $W$  is indecomposable over  $R$ .  $\square$

## §2 Dimension one

The results of the previous section reduce the problem of classifying hypersurface rings of bounded CM type to dimension one. In this section we will deal with those one-dimensional hypersurface rings, as well as the case of non-hypersurface rings of dimension one.

Our problem breaks down according to the multiplicity of the ring. Recall from Theorem 4.18 that over a one-dimensional CM local ring of multiplicity 2 or less, every MCM  $R$ -module is isomorphic to a direct sum of ideals of  $R$ , whence  $R$  has bounded CM type. If on the other hand  $R$  has multiplicity 4 or more, then by Proposition 4.4  $R$  has an overring  $S$  with  $\mu_R(S) \geq 4$ , and then we may apply Theorem 4.2 to obtain an indecomposable MCM module of constant rank  $n$  for every  $n \geq 1$ .

Now we address the troublesome case of multiplicity three for complete equicharacteristic hypersurface rings. Let  $R = k[[x, y]]/(f)$ , where  $k$  is a field and  $f \in (x, y)^3 \setminus (x, y)^4$ . If  $R$  is reduced, we know by Theorem 4.10 that  $R$  has bounded CM type if and only if  $R$  has finite CM type, that is, if and only if  $R$  satisfies the condition

$$(DR2) \quad \frac{\overline{mR+R}}{R} \text{ is cyclic as an } R\text{-module.}$$

Hence we focus on the case where  $R$  is not reduced. Our strategy will be to build finite birational extensions  $S$  of  $R$  satisfying the hypotheses of Theorem 4.2.

**16.7 Theorem.** *Let  $R = k[[x, y]]/(f)$ , where  $k$  is a field and  $f$  is a non-zero non-unit of the formal power series ring  $k[[x, y]]$ . Assume that*

- (i)  $e(R) = 3$ ;
- (ii)  $R$  is not reduced; and
- (iii)  $R \not\cong k[[x, y]]/(x^2y)$ .

*For each positive integer  $n$ ,  $R$  has an indecomposable MCM module of constant rank  $n$ .*

*Proof.* We know  $f$  has order 3 and that its factorization into irreducibles has a repeated factor. Thus, up to a unit, we have either  $f = g^3$  or  $f = g^2h$ , where  $g$  and  $h$  are irreducible elements of  $k[[x, y]]$  of order 1, and, in the second case,  $g$  and  $h$  are relatively prime. After a  $k$ -linear change of variables we may assume that  $g = x$ .

In the second case, if the leading form of  $h$  is not a constant multiple of  $x$ , then by another change of variable [ZS75, Cor. 2, p. 137] we may assume that  $h = y$ . This is the case we have ruled out in (iii).

Suppose now that the leading form of  $h$  is a constant multiple of  $x$ . By Corollary 9.6 to the Weierstrass Preparation Theorem, there exist a unit  $u$  and a non-unit power series  $q \in k[[y]]$  such that  $h = u(x + q)$ . Moreover,  $q \in y^2k[[y]]$  (since the leading form of  $h$  is a constant multiple of  $x$ ). In summary, there are two cases to consider:

- (a)  $f = x^3$ .
- (b)  $f = x^2(x + q)$  for some  $0 \neq q \in y^2k[[y]]$ .

Let  $\mathfrak{m} = (x, y)$  be the maximal ideal of  $R$ . We must show that  $R$  has a finite birational extension  $S$  such that  $\mu_R(S) = 3$  and  $\mathfrak{m}S/\mathfrak{m}$  is not cyclic as an  $R$ -module.

In Case (a) we put  $S = R \left[ \frac{x}{y^2} \right] = R + R \frac{x}{y^2} + R \frac{x^2}{y^4}$ . Clearly  $\mu_R(S) = 3$ , and one checks that  $\frac{\mathfrak{m}S}{\mathfrak{m}^2S + \mathfrak{m}}$  is two-dimensional over  $R/\mathfrak{m}$ .

Assume now that we are in Case (b). One can argue by descending induction that it suffices to consider the case where  $q$  has order 2 in  $k[[y]]$ . (The case of order 1 is the one we have ruled out.) Put  $u = \frac{x}{y^2}$ ,  $v = \frac{x^2 + qx}{y^5}$ , and  $S = R[u, v]$ . Once again this can be seen to satisfy the assumptions of Theorem 4.2, and this finishes the proof.  $\square$

The argument in the proof of Theorem 16.7 does not apply to the  $(D_\infty)$  hypersurface ring  $R = k[[x, y]]/(x^2y) \cong k[[u, v]]/(u^2v - u^3)$ . Adjoining the idempotent  $\frac{u^2}{v^2}$ , one obtains a ring isomorphic to  $k[[v]] \times k[[u, v]]/(u^2)$ , whose integral closure is  $k[[v]] \times \bigcup_{n=1}^{\infty} R \left[ \frac{u}{v^n} \right]$ . From this information one can easily check that  $\mathfrak{m}S/\mathfrak{m}$  is a cyclic  $R$ -module for every finite birational extension  $S$  of  $(R, \mathfrak{m})$ , so we cannot apply Theorem 4.2. However, the calculations in Chapter 13 do indeed verify that the one-dimensional  $(A_\infty)$  and  $(D_\infty)$  hypersurface rings have bounded type. Combining this with Theorem 16.7, we have a complete classification of the complete one-dimensional equicharacteristic hypersurface rings of bounded CM type.

**16.8 Theorem.** *Let  $k$  be an arbitrary field, and let  $R = k[[x, y]]/(f)$  be a complete hypersurface ring of dimension one, where  $f$  is a non-zero non-unit of the power series ring. Then  $R$  has bounded but infinite CM type if and only if  $R$  is isomorphic either to the  $(A_\infty)$  singularity or to the  $(D_\infty)$  singularity.*

Further, if  $R$  has unbounded CM type, then  $R$  has, for each positive integer  $r$ , an indecomposable MCM module of constant rank  $r$ .

Turning now to the non-hypersurface situation in multiplicity 3, we have the following structural result for the relevant rings.

**16.9 Lemma.** *Let  $(R, \mathfrak{m}, k)$  be a one-dimensional local CM ring with  $k$  infinite, and suppose  $e(R) = \mu_R(\mathfrak{m}) = 3$ . Let  $N$  be the nilradical of  $R$ . Then:*

(i)  $N^2 = 0$ .

(ii)  $\mu_R(N) \leq 2$ .

(iii) *If  $\mu_R(N) = 2$ , then  $\mathfrak{m}$  is generated by three elements  $u, v, w$  such that  $\mathfrak{m}^2 = \mathfrak{m}u$  and  $N = Rv + Rw$ .*

(iv) *If  $\mu_R(N) = 1$ , then  $\mathfrak{m}$  is generated by three elements  $u, v, w$  such that  $\mathfrak{m}^2 = \mathfrak{m}u$ ,  $N = Rw$ , and  $vw = w^2 = 0$ .*

*Proof.* Since the residue field of  $R$  is infinite, we can find a minimal reduction for  $\mathfrak{m}$ , that is, a non-zerodivisor  $u \in \mathfrak{m}$  such that  $\mathfrak{m}^{n+1} = u\mathfrak{m}^n$  for all  $n \gg 0$ . Now, using the formula

$$(16.9.1) \quad \mu_R(J) \leq e(R) - e(R/J)$$

for an ideal  $J$  of height 0 in a one-dimensional CM local ring  $R$  (Theorem A.30(ii)), it is straightforward to show (i) and (ii). The other two assertions are easy as well.  $\square$

**16.10 Theorem.** *Let  $k$  be an infinite field. The following is a complete list, up to  $k$ -isomorphism, of the one-dimensional, complete, equicharacteristic, CM local rings with bounded but infinite CM type and with residue field  $k$ :*

- (i) the  $(A_\infty)$  hypersurface singularity  $k[[x, y]]/(x^2)$ ;
- (ii) the  $(D_\infty)$  hypersurface singularity  $k[[x, y]]/(x^2y)$ ;
- (iii) the endomorphism ring  $E$  of the maximal ideal of the  $(D_\infty)$  singularity, which satisfies

$$E \cong k[[x, y, z]]/(yz, x^2 - xz, xz - z^2) \cong k[[a, b, c]]/(ab, ac, c^2).$$

Moreover, if  $(R, \mathfrak{m}, k)$  is a one-dimensional, complete, equicharacteristic CM local ring and  $R$  does not have bounded CM type, then  $R$  has, for each positive integer  $r$ , an indecomposable MCM module of constant rank  $r$ .

*Proof.* The  $(A_\infty)$  and  $(D_\infty)$  hypersurface rings have bounded but infinite CM type by the calculations in Chapter 13. In Example 13.23, we showed that  $E$  has the presentations asserted above, and that  $E$  has countable CM type. More precisely, we used Lemma 4.9 to see that the indecomposable MCM  $E$ -modules are precisely the non-free indecomposable MCM modules over the  $(D_\infty)$  hypersurface ring, whence  $E$  has bounded but infinite CM type as well.

To prove that the list is complete and to prove the “Moreover” statement, assume now that  $(R, \mathfrak{m}, k)$  is a one-dimensional, complete, equicharacteristic CM local ring with  $k$  infinite, and that  $R$  has infinite CM type but does *not* have indecomposable MCM modules of arbitrarily large constant rank. We will show that  $R$  is isomorphic to one of the rings in the statement of the Theorem. As above, we proceed by building finite birational extensions of  $R$  to which we may apply Theorem 4.2.

If  $R$  is a hypersurface ring, Theorem 16.8 tells us that  $R$  is isomorphic to either  $k[[x, y]]/(x^2)$  or  $k[[x, y]]/(x^2y)$ . Thus we assume that  $\mu_R(\mathfrak{m}) \geq 3$ . But  $e(R) \leq 3$  by Theorem 4.2 and we know by Exercise 11.50 that  $e(R) \geq \mu_R(\mathfrak{m}) - \dim R + 1$ . Therefore we may assume that  $e(R) = \mu_R(\mathfrak{m}) = 3$ . Thus we are in the situation of Lemma 16.9. Moreover, we may assume that  $R$  is not reduced, else we are done by Theorem 4.10, so  $R$  has non-trivial nilradical  $N$ .

If  $N$  requires two generators, then by Lemma 16.9(iii), we can find elements  $u, v, w$  in  $R$  such that  $\mathfrak{m} = Ru + Rv + Rw$ ,  $u$  is a minimal reduction of  $\mathfrak{m}$  with  $\mathfrak{m}^2 = mu$ , and  $N = Rv + Rw$ . Put  $S = R\left[\frac{v}{u^2}, \frac{w}{u^2}\right]$ . It is easy to verify (by clearing denominators) that  $\{1, \frac{v}{u^2}, \frac{w}{u^2}\}$  is a minimal generating set for  $S$  as an  $R$ -module, and that the images of  $\frac{v}{u}$  and  $\frac{w}{u}$  form a minimal generating set for  $\frac{\mathfrak{m}S}{\mathfrak{m}}$ . Thus our basic assumption is violated.

We may therefore assume that  $N$  is principal. This is the hard case of the proof; we sketch the argument, and point to [LW05] for the details. Using Lemma 16.9(iv), we once again find elements  $u, v, w$  in  $R$  such that  $\mathfrak{m} = Ru + Rv + Rw$ ,  $u$  is again a minimal reduction of  $\mathfrak{m}$  with  $\mathfrak{m}^2 = mu$ , and  $N = Rw$  with  $vw = w^2 = 0$ .

Since  $v^2 \in mu \subset Ru$ , we see that  $R/Ru$  is a three-dimensional  $k$ -algebra. Further, since  $\bigcap_n (Ru^n) = 0$ , it follows that  $R$  is finitely generated (and free) as a module over the discrete valuation ring  $D = k[[u]]$ . One checks that  $R = D + Dv + Dw$  (and therefore  $\{1, v, w\}$  is a basis for  $R$  as a  $D$ -module).

In order to understand the structure of  $R$  we must analyze the equation that puts  $v^2$  into  $um$ . Thus we write  $v^2 = u^r(\alpha u + \beta v + \gamma w)$ , where  $r \geq 1$  and  $\alpha, \beta, \gamma \in D$ . Since  $u$  is a non-zero-divisor and  $vw = w^2 = 0$ , we see

immediately that  $\alpha = 0$ . Thus we have

$$v^2 = u^r (\beta v + \gamma w),$$

with  $\beta$  and  $\gamma$  in  $D$ . Moreover, at least one of  $\beta$  and  $\gamma$  must be a unit of  $D$ .

If  $r \geq 2$ , put  $S = R[\frac{v}{u^2}, \frac{w}{u^2}]$ . This finite birational extension contradicts our basic assumption, so we must have  $v^2 = u(\beta v + \gamma w)$  with  $\beta, \gamma \in D$  and at least one of  $\beta, \gamma$  a unit of  $D$ . We will produce a hypersurface subring  $A = D[[g]]$  of  $R$  such that  $R = \text{End}_A(\mathfrak{m}_A)$ . We will then show that  $A \cong k[[x, y]]/(x^2 y)$  and the proof will be complete.

In the case where  $\gamma$  is not a unit, set  $A = D[v + w]$ . Then one can show that  $A$  is a local ring with maximal ideal  $\mathfrak{m}_A = Au + A(v + w)$ , and that  $R$  is a finite birational extension of  $A$ . Since  $v(v + w) = (v + w)^2$  and  $w(v + w) = 0$ , we see that  $v$  and  $w$  are in  $\text{End}_A(\mathfrak{m}_A)$ . Since  $\text{End}_A(\mathfrak{m}_A)/A$  is simple (as  $A$  is Gorenstein), it follows that  $R = \text{End}_A(\mathfrak{m}_A)$ .

If on the other hand  $\gamma$  is a unit of  $D$ , we put  $A = D[v] \subseteq R$ . Then  $A$  is a local ring with maximal ideal  $\mathfrak{m}_A = Au + Av$ . (The relevant equation this time is  $v^3 = u\beta v^2$ .) We have  $uw = \gamma^{-1}v^2 - \gamma^{-1}\beta uv \in \mathfrak{m}_A$ . As in the first case, we conclude that  $R = \text{End}_A(\mathfrak{m}_A)$ .

By Lemma 4.9,  $A$  has infinite CM type but does not have indecomposable MCM modules of arbitrarily large constant rank. Moreover,  $A$  cannot have multiplicity 2, since it has a module-finite birational extension of multiplicity greater than 2. By Theorem 16.8,  $A \cong k[[x, y]]/(x^2 y)$ , as desired.  $\square$

### §3 Descent in dimension one

In this section we use the classification theorem in the previous section, together with the results on extended modules in Chapter 2, to show that bounded CM type passes to and from the completion of an equicharacteristic one-dimensional CM local ring  $(R, \mathfrak{m}, k)$  with  $k$  infinite. Contrary to the situation in Chapter 10, we do not assume that  $R$  is excellent with an isolated singularity; indeed, in dimension one this assumption would make  $\widehat{R}$  reduced, in which case finite and bounded CM type are equivalent by Theorem 4.10. We do, however, insist that  $k$  be infinite, in order to use the crucial fact from §2 that failure of bounded CM type implies the existence of indecomposable MCM modules of unbounded *constant* rank and also to use the explicit matrices worked out in Proposition 13.19 and Example 13.23 for the indecomposable MCM modules over  $k[[x, y]]/(x^2y)$ .

**16.11 Theorem.** *Let  $(R, \mathfrak{m}, k)$  be a one-dimensional equicharacteristic CM local ring with completion  $\widehat{R}$ . Assume that  $k$  is infinite. Then  $R$  has bounded CM type if and only if  $\widehat{R}$  has bounded CM type. If  $R$  has unbounded CM type, then  $R$  has, for each  $r$ , an indecomposable MCM module of constant rank  $r$ .*

*Proof.* Assume that  $\widehat{R}$  does not have bounded CM type. Fix a positive integer  $r$ . By Theorem 16.10 we know that  $\widehat{R}$  has an indecomposable MCM module  $M$  of constant rank  $r$ . By Corollary 2.8 there is a finitely generated  $R$ -module  $N$ , necessarily MCM and with constant rank  $r$ , such that  $\widehat{N} \cong M$ . Obviously  $N$  too must be indecomposable.

Assume from now on that  $\widehat{R}$  has bounded CM type. If  $\widehat{R}$  has *finite* CM type, the same holds for  $R$  by Theorem 10.1. Therefore we assume that  $\widehat{R}$  has infinite CM type. Then  $\widehat{R}$  is isomorphic to one of the three rings of Theorem 16.10.

If  $\widehat{R} \cong k[[x, y]]/(x^2)$ , then  $e(R) = e(\widehat{R}) = 2$ , and  $R$  has bounded CM type by Theorem 4.18. Suppose for the moment that we have verified bounded CM type for any local ring  $S$  whose completion is isomorphic to  $E$ . If, now,  $\widehat{R} \cong k[[x, y]]/(x^2y)$ , put  $S = \text{End}_R(\mathfrak{m})$ . Then  $\widehat{S} \cong E$ , whence  $S$  has bounded CM type. Therefore so has  $R$ , by Lemma 4.9. Thus we assume that  $\widehat{R} \cong E$ .

Our plan is to examine each of the indecomposable non-free  $E$ -modules and then use Corollary 2.8 to determine exactly which MCM  $E$ -modules are extended from  $R$ . As we saw in Example 13.23, those indecomposable MCM modules are the cokernels of the following matrices over  $T = k[[x, y]]/(x^2y)$ :

$$\begin{array}{c}
 [y]; \quad [xy]; \quad [x]; \quad [y^2]; \\
 \alpha = \begin{bmatrix} y & x^k \\ 0 & -y \end{bmatrix}; \quad \beta = \begin{bmatrix} xy & x^{k+1} \\ 0 & -xy \end{bmatrix}; \quad \gamma = \begin{bmatrix} xy & x^k \\ 0 & -y \end{bmatrix}; \quad \delta = \begin{bmatrix} y & x^{k+1} \\ 0 & -xy \end{bmatrix}.
 \end{array}$$

Let  $\mathfrak{P} = (x)$  and  $\mathfrak{Q} = (y)$  be the two minimal prime ideals of  $T$ . Note that  $T_{\mathfrak{P}} \cong k((y))[x]/(x^2)$  and  $T_{\mathfrak{Q}} \cong k((x))$ . With the exception of  $U := \text{cok}[x]$  and  $V := \text{cok}[xy]$ , each of the  $E$ -modules listed above is generically free. The ranks are given in the following table.

$\varphi$	$\text{rank}_{\mathfrak{P}} \text{cok } \varphi$	$\text{rank}_{\mathfrak{Q}} \text{cok } \varphi$
$[x^2]$	1	0
$[y]$	0	1
$\alpha$	1	0
$\beta$	1	2
$\gamma$	1	1
$\delta$	1	1

Let  $M$  be a MCM  $\widehat{R}$ -module, and write

$$(16.11.1) \quad M \cong \left( \bigoplus_{i=1}^a A_i \right) \oplus \left( \bigoplus_{j=1}^b B_j \right) \oplus \left( \bigoplus_{k=1}^c C_k \right) \oplus \left( \bigoplus_{l=1}^d D_l \right) \oplus U^{(e)} \oplus V^{(f)},$$

where the  $A_i, B_j, C_k, D_l$  are indecomposable generically free modules, of ranks  $(1,0), (0,1), (1,1), (1,2)$  respectively, and again  $U = \text{cok}[x]$  and  $V = \text{cok}[xy]$ .

Suppose first that  $R$  is a domain. Then  $M$  is extended if and only if  $a = b + d$  and  $e = f = 0$ . Now the indecomposable MCM  $R$ -modules are those whose completions have  $(a, b, c, d, e, f)$  minimal and non-trivial with respect to these relations. (We are implicitly using Corollary 1.15 here.) The only possibilities are  $(0, 0, 1, 0, 0, 0), (1, 1, 0, 0, 0, 0),$  and  $(1, 0, 0, 1, 0, 0),$  and we conclude that the indecomposable MCM  $R$ -modules have rank 1 or 2.

Next suppose that  $R$  is reduced but not a domain. Then  $R$  has exactly two minimal prime ideals, and we see from Corollary 2.8 that every generically free  $\widehat{R}$ -module is extended from  $R$ ; however, neither  $U$  nor  $V$  can be a direct summand of an extended module. In this case, the indecomposable

MCM  $R$ -modules are generically free, with ranks  $(1, 0), (0, 1), (1, 1)$  and  $(1, 2)$  at the minimal prime ideals.

Finally, we assume that  $R$  is not reduced. We must now consider the two modules  $U$  and  $V$  that are not generically free. We will see that  $U = \text{cok}[x]$  is always extended and that  $V = \text{cok}[xy]$  is extended if and only if  $R$  has two minimal prime ideals. Note that  $U \cong Tx^2 = Ex^2$  (the nilradical of  $E = \widehat{R}$ ), while  $V \cong Tx = Ex$ .

The nilradical  $N$  of  $R$  is of course contained in the nilradical  $Exy$  of  $\widehat{R}$ . Moreover, since  $Exy \cong E/(x, z)$  is a faithful module over  $E/(x, z) \cong k[[y]]$ , every non-zero submodule of  $Exy$  is isomorphic to  $Exy$ . In particular,  $N\widehat{R} \cong Exy$ . This shows that  $U$  is extended.

Next we deal with  $V$ . The kernel of the surjective map  $Ex \rightarrow Exy$ , given by multiplication by  $y$ , is  $Ex^2$ . Thus we have a short exact sequence

$$(16.11.2) \quad 0 \rightarrow Ex^2 \rightarrow V \xrightarrow{y} U \rightarrow 0.$$

Observe that  $Ex^2 = Tx^2 \cong \text{cok}[y]$  is generically free of rank  $(0, 1)$ . Let  $K$  be the common total quotient ring of  $T$  and  $\widehat{R}$ . Then  $K \otimes_E Ex^2$  is a projective  $K$ -module, and as  $K$  is Gorenstein, (16.11.2) splits when tensored up to  $K$ . In particular, this gives

$$K \otimes_E V \cong (K \otimes_E Ex^2) \oplus (K \otimes_E U).$$

If, now,  $R$  has two minimal primes, then every generically free  $\widehat{R}$ -module is extended, by Corollary 2.8. In particular  $Ex^2$  is extended, and by Lemma 2.7 so is  $V$ . Thus every indecomposable MCM  $\widehat{R}$ -module is extended, and  $R$  has bounded CM type.

If, on the other hand,  $R$  has just one minimal prime ideal, then the module  $M$  in (16.11.1) is extended if and only if  $a = b + d + f$ . The  $\widehat{R}$ -modules corresponding to indecomposable MCM  $R$ -modules are therefore  $U, V \oplus W$ , where  $W$  is some generically free module of rank  $(0, 1)$ , and the modules of constant rank 1 and 2 described above.  $\square$

Proving descent of bounded CM type in general seems quite difficult. Part of the difficulty lies in the fact that, in general, there is no bound on the number of indecomposable MCM  $\widehat{R}$ -modules required to decompose the completion of an indecomposable MCM  $R$ -module. Thus the argument of Theorem 10.1, while sufficient for showing descent of finite CM type, is not enough for bounded CM type.

Here is an example to illustrate. Recall that for a two-dimensional normal domain, the divisor class group essentially controls which modules are extended to the completion. Precisely (Proposition 2.15), if  $R$  and  $\widehat{R}$  are both normal domains, then a torsion-free  $\widehat{R}$ -module  $N$  is extended from  $R$  if and only if  $\text{cl}(N)$  is in the image of the natural map on divisor class groups  $\text{Cl}(R) \rightarrow \text{Cl}(\widehat{R})$ .

**16.12 Example.** Let  $R$  be a complete local two-dimensional normal domain containing a field, and assume that the divisor class group  $\text{Cl}(R)$  has an element  $\alpha$  of infinite order. For example, one might take the ring of Lemma 2.16.

By Heitmann's theorem [Hei93], there is a unique factorization domain  $A$  contained in  $R$  such that  $\widehat{A} = R$ . Choose, for each integer  $n$ , a divisorial ideal  $I_n$  corresponding to  $n\alpha \in \text{Cl}(\widehat{A})$ . For each  $n \geq 1$ , let  $M_n = I_n \oplus N_n$ , where  $N_n$  is the direct sum of  $n$  copies of  $I_{-1}$ . Then  $M_n$  has trivial divisor

class and therefore is extended from  $A$  by Proposition 2.15. However, no non-trivial proper direct summand of  $M_n$  has trivial divisor class, and it follows that  $M_n$  (a direct sum of  $n + 1$  indecomposable  $\widehat{A}$ -modules) is extended from an indecomposable MCM  $A$ -module.

It is important to note that the example above does not give a counterexample to descent of bounded CM type, but merely points out one difficulty in studying descent.

## §4 Exercises

**16.13 Exercise.** Let  $A$  be a local ring. Prove that there is an upper bound on the multiplicities of the indecomposable MCM  $A$ -modules if and only if there is a bound on their minimal numbers of generators.

**16.14 Exercise.** Complete the proof of Theorem 16.7.

**16.15 Exercise.** Show that the argument of Theorem 16.7 does not apply to  $R = k[[u, v]]/(u^2v - v^3)$ , since  $\mathfrak{m}S/\mathfrak{m}$  is a cyclic  $R$ -module for every finite birational extension  $S$  of  $R$ .

**16.16 Exercise.** Prove the inequality (16.9.1):  $\mu_R(J) \leq e(R) - e(R/J)$  for an ideal  $J$  of height zero in a one-dimensional CM local ring  $R$ .

**16.17 Exercise.** Finish the proof of Lemma 16.9.

# A

## Appendix: Basics

Here we collect some basic definitions and results that are necessary but somewhat peripheral to the main themes of the book. Some of the results are stated without proof; for these, one can find proofs in [Mat89]. We refer to [Mat89] also for any unexplained terminology.

### §1 Depth, syzygies, and Serre's conditions

Throughout this section we let  $(R, \mathfrak{m}, k)$  be a local ring.

**A.1 Definition.** Let  $M$  be a finitely generated  $R$ -module. The *depth* of  $M$  is given by

$$\text{depth}_R(M) = \inf \{n \mid \text{Ext}_R^n(k, M) \neq 0\}.$$

Note that  $\text{depth}_R(0) = \inf(\emptyset) = \infty$ . Conversely, non-zero modules have finite depth:

**A.2 Proposition.** *Let  $M$  be a non-zero finitely generated  $R$ -module.*

- (i)  $\text{depth}_R(M) < \infty$ .
- (ii)  $\text{depth}_R(M) = \sup \{n \mid \text{there is an } M\text{-regular sequence } (x_1, \dots, x_n) \text{ in } \mathfrak{m}\}$ .
- (iii) *Every maximal  $M$ -regular sequence in  $\mathfrak{m}$  has length  $n$ .*
- (iv)  $\text{depth}_R(M) \leq \dim(R/\mathfrak{p})$  for every  $\mathfrak{p} \in \text{Ass}(M)$ . In particular,  $\text{depth}(M) \leq \dim(M) \leq \dim(R)$ .

(v) If  $(S, \mathfrak{n}) \longrightarrow (R, \mathfrak{m})$  is a local homomorphism and  $R$  is finitely generated as an  $S$ -module, then  $\text{depth}_S(M) = \text{depth}_R(M)$ .

(vi) If  $\mathfrak{p} \in \text{Spec}(R)$ , then  $\text{depth}_{R_{\mathfrak{p}}}(M_{\mathfrak{p}}) = 0 \iff \mathfrak{p} \in \text{Ass}(M)$ .  $\square$

When the base ring  $R$  is clear, or when, e.g. as in item (v) it is irrelevant, we often omit the subscript and write “ $\text{depth}(M)$ ”.

The next result is called the *Depth Lemma*. It follows easily from the long exact sequence of  $\text{Ext}$ .

**A.3 Lemma.** *Let  $0 \longrightarrow U \longrightarrow V \longrightarrow W \longrightarrow 0$  be a short exact sequence of finitely generated  $R$ -modules.*

(i) *If  $\text{depth}(W) < \text{depth}(V)$ , then  $\text{depth}(U) = \text{depth}(W) + 1$ .*

(ii)  $\text{depth}(U) \geq \min\{\text{depth}(V), \text{depth}(W)\}$ .

(iii)  $\text{depth}(V) \geq \min\{\text{depth}(U), \text{depth}(W)\}$ .  $\square$

See [Mat89, Theorem 19.1] for a proof of the next result, the Auslander-Buchsbaum Formula. We write  $\text{pd}_R(M)$  for the projective dimension of an  $R$ -module  $M$ .

**A.4 Theorem** (Auslander-Buchsbaum Formula). *Let  $M$  be an  $R$ -module of finite projective dimension. Then  $\text{depth}(M) + \text{pd}_R(M) = \text{depth}(R)$ .*

**A.5 Definition.** Let  $M$  be a finitely generated module over a local ring  $(R, \mathfrak{m})$ , and let  $n$  be a non-negative integer. Then  $M$  satisfies *Serre’s condition*  $(S_n)$  provided

$$\text{depth}_{R_{\mathfrak{p}}}(M_{\mathfrak{p}}) \geq \min\{n, \dim(R_{\mathfrak{p}})\} \text{ for every } \mathfrak{p} \in \text{Spec}(R).$$

**A.6 Warning.** Our terminology differs from that of EGA [GD65, Definition 5.7.2] and Bruns-Herzog [BH93, Section 2.1], where “ $\dim(R_{\mathfrak{p}})$ ” is replaced by “ $\dim(M_{\mathfrak{p}})$ ”. Notice, for example, that by the EGA definition every finite-length module would satisfy  $(S_n)$  for all  $n$ , while this is certainly not the case with the definition we use. Of course, the two conditions agree for the ring itself.

The  $(S_n)$  conditions allow characterizations of reducedness and normality.

**A.7 Proposition.** *The ring  $R$  is reduced if and only if the following hold.*

(i)  *$R$  satisfies  $(S_1)$ , and*

(ii)  *$R_{\mathfrak{p}}$  is a field for every minimal prime ideal  $\mathfrak{p}$ .* □

**A.8 Proposition** (Serre's criterion). *These are equivalent.*

(i)  *$R$  is a normal domain.*

(ii)  *$R$  satisfies  $(S_2)$ , and  $R_{\mathfrak{p}}$  is a regular local ring for each prime ideal  $\mathfrak{p}$  of height at most one.* □

We will say that a finitely generated module  $M$  over a ring  $A$  is an  $r^{\text{th}}$  syzygy (of  $N$ ), provided there is an exact sequence

$$(A.8.1) \quad 0 \longrightarrow M \longrightarrow F_{r-1} \longrightarrow \dots \longrightarrow F_0 \longrightarrow N \longrightarrow 0,$$

where  $N$  is a finitely generated module and each  $F_i$  is a finitely generated projective  $A$ -module.

Syzygies are unique up to projective summands, by Schanuel's Lemma:

**A.9 Lemma** (Schanuel's Lemma). *Let  $M_1$  and  $M_2$  be  $r^{\text{th}}$  syzygies of a finitely generated  $N$  over a Noetherian ring  $A$ . Then there are finitely generated projective  $A$ -modules  $G_1$  and  $G_2$  such that  $M_1 \oplus G_2 \cong M_2 \oplus G_1$ .*

If  $R$  is local and each  $F_i$  is chosen minimally, then the resolution is essentially unique. In particular, the syzygies are unique up to isomorphism, and we let  $\text{syz}_r^R(N)$  denote the  $r^{\text{th}}$  syzygy with respect to a minimal resolution. We define  $\text{red}\text{syz}_r^R(N)$  to be the *reduced  $r^{\text{th}}$  syzygy*, obtained from  $\text{syz}_r^R(N)$  by deleting all non-zero free direct summands.

**A.10 Definition.** Let  $A$  be a Noetherian ring and  $M$  a finitely generated  $A$ -module. Say that  $M$  is *torsion-free* if every non-zero-divisor in  $A$  is a non-zero-divisor on  $M$ . Equivalently, the natural map  $M \rightarrow K \otimes_A M$ , where  $K$  is the total quotient ring, is injective.

**A.11 Definition.** Let  $A$  be a Noetherian ring and  $M$  a finitely generated  $A$ -module. Set  $M^* = \text{Hom}_A(M, A)$ , the *dual* of  $M$ , and  $M^{**} = \text{Hom}_A(M^*, A)$ , the *bidual*. Define

$$\sigma_M: M \rightarrow M^{**}$$

by  $\sigma_M(x)(f) = f(x)$  for  $x \in M$  and  $f \in M^*$ . Say that

- (i)  $M$  is *torsionless* if  $\sigma_M$  is injective, and
- (ii)  $M$  is *reflexive* if  $\sigma_M$  is bijective.

**A.12 Proposition.** *Let  $A$  be a Noetherian ring and let  $M$  be a finitely generated  $A$ -module.*

- (i)  $M$  is *torsionless* if and only if  $M$  is a first syzygy.

(ii) If  $M$  is reflexive, then  $M$  is a second syzygy.

(iii) Reflexivity implies torsionlessness implies torsion-freeness.

*Proof.* First assume that  $M$  is torsionless. Let  $f_1, \dots, f_n$  be  $A$ -module generators for  $M^* = \text{Hom}_A(M, A)$ , and define  $\varphi: M \rightarrow A^{(n)}$  by  $\varphi(x) = (f_1(x), \dots, f_n(x))$ . If  $\varphi(x) = 0$ , then  $f(x) = 0$  for every  $f \in M^*$ , so  $\sigma(x) = 0$ . Thus  $\varphi$  is injective, and  $M$  is a first syzygy. If on the other hand there is an injective homomorphism  $\psi: M \rightarrow A^{(m)}$ , let  $\pi_1, \dots, \pi_m: A^{(m)} \rightarrow A$  be the projections. For any non-zero  $x \in M$ , we must have  $\pi_j \psi(x) \neq 0$  for some  $j$ , so  $\pi_j \psi \in M^*$  does not vanish on  $x$  and  $x \notin \ker \sigma$ .

For (ii), choose a free presentation  $G \rightarrow F \rightarrow M^* \rightarrow 0$  for the dual. Apply  $\text{Hom}_A(-, A)$  and use the left-exactness of  $\text{Hom}$  to obtain an exact sequence  $0 \rightarrow M^{**} \rightarrow F^* \rightarrow G^*$ . If  $M \cong M^{**}$ , this exhibits  $M$  as a second syzygy.

For the last statement, note that reflexivity clearly implies torsionlessness. If  $M$  is torsionless, then by (i)  $M$  is a submodule of a free module, so non-zerodivisors on  $A$  are non-zerodivisors on  $M$ .  $\square$

The converse of part (ii) of Proposition A.12 does not hold in general, but is true under a mild condition on the ring: that  $R$  is Gorenstein in codimension one. We explain this now using the following result, which is proved, but not quite stated correctly, in [EG85].

Recall that maximal Cohen-Macaulay modules over Gorenstein local rings are reflexive (by, for example, Theorem 11.5).

**A.13 Theorem.** *Let  $M$  be a finitely generated  $R$ -module satisfying Serre's condition  $(S_n)$ , where  $n \geq 1$ . Assume*

(i)  $R$  satisfies  $(S_{n-1})$ , and

(ii)  $R_{\mathfrak{p}}$  is Gorenstein for every prime  $\mathfrak{p}$  with  $\dim(R_{\mathfrak{p}}) \leq n - 1$ .

Then there is an exact sequence

$$(A.13.1) \quad 0 \longrightarrow M \xrightarrow{\alpha} F \longrightarrow N \longrightarrow 0,$$

in which  $F$  is a finitely generated free module and  $N$  satisfies  $(S_{n-1})$ .

*Proof.* We start with an exact sequence

$$(A.13.2) \quad 0 \longrightarrow K \longrightarrow G \longrightarrow M^* \longrightarrow 0,$$

where  $G$  is a finitely generated free module and  $M^* = \text{Hom}_R(M, R)$ . Put  $F = G^*$ , and dualize (A.13.2), getting an exact sequence

$$(A.13.3) \quad 0 \longrightarrow M^{**} \xrightarrow{\beta} F \longrightarrow K^* \longrightarrow \text{Ext}_R^1(M^*, R) \longrightarrow 0.$$

Let  $\sigma: M \longrightarrow M^{**}$  be the canonical map, let  $\alpha = \beta\sigma$ , and put  $N = \text{cok } \alpha$ .

To verify exactness of (A.13.1), we just have to show that  $\sigma$  is one-to-one. Supposing, by way of contradiction, that  $L = \ker(\sigma)$  is non-zero, we choose  $\mathfrak{p} \in \text{Ass}(L)$ . Then  $\text{depth}(L_{\mathfrak{p}}) = 0$ . Given any minimal prime  $\mathfrak{q}$ , we know  $R_{\mathfrak{q}}$  is a zero-dimensional Gorenstein ring (since  $n \geq 1$ ), and  $M_{\mathfrak{q}}$  is a MCM  $R_{\mathfrak{q}}$ -module, whence  $\sigma_{\mathfrak{q}}$  is an isomorphism. Thus  $L_{\mathfrak{q}} = 0$  for each minimal prime  $\mathfrak{q}$ . In particular,  $\dim(R_{\mathfrak{p}}) \geq 1$ , so  $\text{depth}(M_{\mathfrak{p}}) \geq 1$ . But this contradicts the fact that  $\text{depth}(L_{\mathfrak{p}}) = 0$ .

Let  $\mathfrak{p}$  be a prime of height  $h$ . If  $h \leq n - 1$ , we need to show that  $N_{\mathfrak{p}}$  is MCM. Since  $R_{\mathfrak{p}}$  is Gorenstein and  $M_{\mathfrak{p}}$  is MCM, the canonical map  $\sigma_{\mathfrak{p}}$  is an isomorphism. Also,  $M_{\mathfrak{p}}^*$  is MCM, so  $\text{Ext}_{R_{\mathfrak{p}}}^1(M_{\mathfrak{p}}^*, R_{\mathfrak{p}}) = 0$ . The upshot of all of

this is that  $N_{\mathfrak{p}} \cong K_{\mathfrak{p}}^*$ . Now (A.13.2) shows that  $K_{\mathfrak{p}}$  is MCM, and therefore so is its dual  $K_{\mathfrak{p}}^*$ .

To complete the proof that  $N$  satisfies  $(S_{n-1})$ , we assume now that  $h \geq n$ . We need to show that  $\text{depth}_{R_{\mathfrak{p}}}(N_{\mathfrak{p}}) \geq n - 1$ . Suppose  $\text{depth}_{R_{\mathfrak{p}}}(N_{\mathfrak{p}}) < n - 1$ . Since  $\text{depth}_{R_{\mathfrak{p}}}(F_{\mathfrak{p}}) \geq n - 1$ , the Depth Lemma A.3, applied to (A.13.1), shows that  $\text{depth}_{R_{\mathfrak{p}}}(M_{\mathfrak{p}}) = 1 + \text{depth}_{R_{\mathfrak{p}}}(N_{\mathfrak{p}}) < n$ , a contradiction.  $\square$

**A.14 Corollary.** *Let  $(R, \mathfrak{m})$  be a local ring,  $M$  a finitely generated  $R$ -module and  $n$  a positive integer. Assume  $R$  satisfies Serre's condition  $(S_n)$  and  $R_{\mathfrak{p}}$  is Gorenstein for each prime  $\mathfrak{p}$  of height at most  $n - 1$ . These are equivalent.*

(i)  $M$  is an  $n^{\text{th}}$  syzygy.

(ii)  $M$  satisfies  $(S_n)$ .

*Proof.* (i)  $\implies$  (ii) by the Depth Lemma, and (ii)  $\implies$  (i) by Theorem A.13.  $\square$

**A.15 Corollary.** *Let  $(R, \mathfrak{m})$  be a local ring that satisfies  $(S_2)$  and is Gorenstein in codimension one. These are equivalent for a finitely generated  $R$ -module  $M$ .*

(i)  $M$  is reflexive.

(ii)  $M$  satisfies  $(S_2)$ .

(iii)  $M$  is a second syzygy.

**A.16 Corollary.** *Let  $R$  be a local normal domain and  $M$  a finitely generated  $R$ -module. If  $M$  is MCM, then  $M$  is reflexive. The converse holds if  $R$  has dimension two.*  $\square$

**A.17 Corollary.** *Let  $(R, \mathfrak{m})$  be a CM local ring of dimension  $d$ , and assume that  $R_{\mathfrak{p}}$  is Gorenstein for every prime ideal  $\mathfrak{p} \neq \mathfrak{m}$ . These are equivalent, for a finitely generated  $R$ -module  $M$ .*

(i)  $M$  is MCM.

(ii)  $M$  is a  $d^{\text{th}}$  syzygy. □

**A.18 Remark.** The hypothesis that  $R$  be Gorenstein on the punctured spectrum cannot be weakened, at least when  $R$  has a canonical module (or, more generally, a *Gorenstein module* [Sha70], that is, a finitely generated module whose completion is a direct sum of copies of the canonical module  $\omega_{\widehat{R}}$ ). Let  $(R, \mathfrak{m})$  be a  $d$ -dimensional CM local ring having a canonical module  $\omega$ . If  $\omega$  is a  $d^{\text{th}}$  syzygy, then  $R$  is Gorenstein on the punctured spectrum. To see this, we build an exact sequence

$$(A.18.1) \quad 0 \longrightarrow \omega \longrightarrow F \longrightarrow M \longrightarrow 0,$$

where  $F$  is free and  $M$  is a  $(d - 1)^{\text{st}}$  syzygy. Now let  $\mathfrak{p}$  be any non-maximal prime ideal. Since  $M_{\mathfrak{p}}$  is MCM and  $\omega_{\mathfrak{p}}$  is a canonical module for  $R_{\mathfrak{p}}$ , (A.18.1) splits when localized at  $\mathfrak{p}$  (apply Proposition 11.3). But then  $\omega_{\mathfrak{p}}$  is free, and it follows that  $R_{\mathfrak{p}}$  is Gorenstein. (We thank Bernd Ulrich for showing us this argument (cf. also [LW00, Lemma 1.4]).)

## §2 Multiplicity and rank

In this section we gather the definitions and basic results on multiplicity and rank that are used in the body of the text. See Chapter 14 of [Mat89] for proofs.

Throughout we let  $(R, \mathfrak{m}, k)$  be a local ring of dimension  $d$ , let  $I$  be an  $\mathfrak{m}$ -primary ideal of  $R$ , and let  $M$  be a finitely generated  $R$ -module.

**A.19 Definition.** The *multiplicity* of  $I$  on  $M$  is defined by

$$e_R(I, M) = \lim_{n \rightarrow \infty} \frac{d!}{n^d} \ell_R(M/I^n M),$$

where  $\ell_R(-)$  denotes length as an  $R$ -module. In particular we set  $e_R(M) = e_R(\mathfrak{m}, M)$  and call it the *multiplicity of  $M$* . Finally, we denote  $e(R) = e_R(R)$  and call it the *multiplicity of the ring  $R$* .

It is standard that the Hilbert-Samuel function  $n \mapsto \ell_R(M/I^{n+1}M)$  is eventually given by a polynomial in  $n$  of degree equal to  $\dim M$ . Thus  $e_R(I, M)$  is the coefficient of  $n^d$  in this polynomial, and  $e_R(I, M) \neq 0$  if and only if  $\dim M = d$ . In particular if  $d = 0$  then  $e_R(I, M) = \ell_R(M)$  for any  $I$ .

It follows immediately from the definition that if  $I \subseteq J$  are two  $\mathfrak{m}$ -primary ideals, then  $e_R(I, M) \geq e_R(J, M)$ . One case where equality holds is particularly useful.

**A.20 Definition.** Let  $I \subseteq J$  be ideals of  $R$  (not necessarily  $\mathfrak{m}$ -primary). We say  $I$  is a *reduction* of  $J$  if

$$I^{n+1} = JI^n$$

for some  $n \geq 1$ . Equivalently,  $I^{n+k} = J^k I^n$  for all  $n \gg 0$  and all  $k \geq 1$ .

The proof of the next result is a short calculation from the definitions.

**A.21 Proposition.** Let  $I \subseteq J$  be  $\mathfrak{m}$ -primary ideals of  $R$  such that  $I$  is a reduction of  $J$ . Then  $e_R(I, M) = e_R(J, M)$ .  $\square$

Reductions are often better-behaved ideals. In particular, under a mild assumption there is a reduction which is generated by a system of parameters. (Recall that a system of parameters consists of  $d = \dim(R)$  elements generating an  $\mathfrak{m}$ -primary ideal.) See [Mat89, Theorem 14.14] for a proof.

**A.22 Theorem.** *Assume that the residue field  $k$  is infinite. Then there exists a system of parameters  $x_1, \dots, x_d$  contained in  $I$  such that  $(x_1, \dots, x_d)$  is a reduction of  $I$ . Indeed, if  $I$  is generated by  $a_1, \dots, a_t$ , then the  $x_i$  may be taken to be “sufficiently general” linear combinations  $x_i = \sum r_{ij} a_j$  (for  $r_{ij} \in R$  avoiding the common zeros of a finite list of polynomials).  $\square$*

The restriction on the residue field is rarely an obstacle in practice. For many questions, the general case can be reduced to this one by passing to a gonflement  $R' = R[x]_{\mathfrak{m}R[x]}$  (see Chapter 10, §3). Since  $R \rightarrow R'$  is faithfully flat, it is easy to check that the association  $I \mapsto IR'$  preserves containment, height, number of generators, and colength if  $I$  is  $\mathfrak{m}$ -primary. It thus preserves multiplicities. Since the residue field of  $R'$  is  $R'/\mathfrak{m}R' = (R[x]/\mathfrak{m}R[x])_{\mathfrak{m}R[x]}$ , the quotient field of  $(R/\mathfrak{m})[x]$ , it is an infinite field.

Theorem A.22 reduces many computations of multiplicity to the case of ideals generated by systems of parameters. The next results relate multiplicities over  $R$  to multiplicities calculated modulo a system of parameters.

**A.23 Theorem.** *Let  $\mathbf{x} = x_1, \dots, x_d$  be a system of parameters contained in  $I$ , and set  $\bar{R} = R/(\mathbf{x})$ ,  $\bar{I} = I/(\mathbf{x})$ , and  $\bar{M} = M/\mathbf{x}M$ . If  $x_i \in I^{s_i}$  for each  $i$ , then*

$$\ell_R(\bar{M}) = e_{\bar{R}}(\bar{I}, \bar{M}) \geq s_1 \cdots s_d e_R(I, M).$$

*In particular, if  $x_i \in \mathfrak{m}^s$  for all  $i$ , then  $\ell_R(\bar{M}) \geq s^d e_R(M)$ .  $\square$*

**A.24 Corollary.** *Let  $(S, \mathfrak{n})$  be a regular local ring and  $f \in S$  a non-zero non-unit. Then the multiplicity of the hypersurface ring  $R = S/(f)$  is the largest integer  $s$  such that  $f \in \mathfrak{n}^s$ .  $\square$*

The behavior of multiplicity for ideals generated by systems of parameters is most satisfactory in the Cohen-Macaulay case. This is [Mat89, Theorems 14.10 and 14.11].

**A.25 Theorem.** *Let  $\mathbf{x}$  be a system of parameters for  $R$ . Then*

$$\ell_R(M/\mathbf{x}M) \geq e_R((\mathbf{x}), M),$$

*and if  $\mathbf{x}$  is a regular sequence on  $M$  then equality holds.  $\square$*

Here are a few more basic facts.

**A.26 Proposition.** *Let  $0 \rightarrow M' \rightarrow M \rightarrow M'' \rightarrow 0$  be a short exact sequence of finitely generated  $R$ -modules. Then  $e_R(I, M) = e_R(I, M') + e_R(I, M'')$ .  $\square$*

**A.27 Proposition.** *We have*

$$e_R(I, M) = \sum_{\mathfrak{p}} \ell_{R_{\mathfrak{p}}}(M_{\mathfrak{p}}) \cdot e_{R/\mathfrak{p}}(\bar{I}, R/\mathfrak{p}),$$

*where the sum is over all minimal primes  $\mathfrak{p}$  of  $R$  such that  $\dim(R/\mathfrak{p}) = d$ , and  $\bar{I}$  denotes the image of  $I$  in  $R/\mathfrak{p}$ . If in particular  $R$  is a domain with quotient field  $K$ , then  $e_R(I, M) = \dim_K(K \otimes_R M)$ .  $\square$*

The quantity  $\dim_K(K \otimes_R M)$  in Proposition A.27 is known as the *rank* of  $M$ . We extend this notion as follows.

**A.28 Definition.** Let  $A$  be a Noetherian ring and  $N$  a finitely generated  $A$ -module. Denote by  $K$  the total quotient ring of  $A$ , obtained by inverting the complement of the associated primes of  $A$ . Say that  $N$  has *constant rank* provided  $K \otimes_A N$  is a free  $K$ -module. If  $K \otimes_A N \cong K^{(r)}$  (equivalently,  $N_{\mathfrak{p}} \cong A_{\mathfrak{p}}^{(r)}$  for every  $\mathfrak{p} \in \text{Ass}(A)$ ), we say that  $N$  has constant rank  $r$ .

The following useful fact follows immediately from the “associativity formula” in Proposition A.27 and the additivity of  $e(-)$  along short exact sequences.

**A.29 Proposition.** *Assume that  $R$  is reduced and that  $M$  has constant rank. Then*

$$\mu_R(M) \geq e_R(M) = e(R) \cdot r,$$

and equality holds on the left if and only if  $M \cong R^{(r)}$ . □

In dimension one, the multiplicity of  $R$  carries a great deal of structural information. Part (ii) of the next result goes back to Akizuki [Aki37].

**A.30 Theorem.** *Assume  $d = 1$ .*

- (i) *The multiplicity of  $R$  is the minimal number of generators required for high powers of  $\mathfrak{m}$ .*
- (ii) *If  $R$  is Cohen-Macaulay, then  $e(R)$  is the sharp bound on  $\mu_R(I)$  as  $I$  runs over all ideals of  $R$ . For ideals  $I$  of height 0, we even have*

$$\mu_R(I) \leq e(R) - e(R/I).$$

- (iii) *If  $R$  is Cohen-Macaulay, then  $e(R)$  is the sharp bound on  $\mu_R(S)$  for  $S$  a finite birational extension of  $R$ .*

(iv) If  $R$  is reduced and the integral closure  $\overline{R}$  is finitely generated over  $R$ , then  $e(R) = \mu_R(\overline{R})$ .

*Proof.* Since  $\dim R = 1$ , we have  $\ell_R(R/\mathfrak{m}^{n+1}) = en - p$  for  $n \gg 0$  and some  $p \in \mathbb{Z}$ . Since also  $\ell_R(R/\mathfrak{m}^{n+1}) = \ell_R(R/\mathfrak{m}^n) + \mu_R(\mathfrak{m}^n)$ , part (i) follows.

For (ii), we assume that  $k$  is infinite. Consider first the case in which  $I$  is  $\mathfrak{m}$ -primary. By Theorem A.22, there exists a non-zerodivisor  $x \in \mathfrak{m}$  such that  $x\mathfrak{m}^n = \mathfrak{m}^{n+1}$  for  $n \gg 0$ . The surjective homomorphism  $R \rightarrow (x)/xI$  sending 1 to the image of  $x$  shows that  $\ell_R(R/I) \geq \ell_R((x)/xI)$ . We therefore compute

$$\begin{aligned} \mu_R(I) &= \ell_R(I/\mathfrak{m}I) \\ &= \ell_R(R/\mathfrak{m}I) - \ell_R(R/I) \\ &= \ell_R(R/xI) - \ell_R(\mathfrak{m}I/xI) - \ell_R(R/I) \\ &= \ell_R(R/(x)) + \ell_R((x)/xI) - \ell_R(\mathfrak{m}I/xI) - \ell_R(R/I) \\ &\leq \ell_R(R/(x)) - \ell_R(\mathfrak{m}I/xI) \\ &\leq e(R). \end{aligned}$$

If now  $I$  is not  $\mathfrak{m}$ -primary, we find using the Artin-Rees Lemma an integer  $r$  such that for all  $k \geq 0$  we have  $I \cap \mathfrak{m}^{r+k} = (I \cap \mathfrak{m}^r)\mathfrak{m}^k \subseteq I\mathfrak{m}$ . As  $I + \mathfrak{m}^r$  is  $\mathfrak{m}$ -primary, the previous case implies

$$\begin{aligned} e(R) &\geq \mu_R(I + \mathfrak{m}^r) \\ &= \ell_R\left(\frac{I + \mathfrak{m}^r}{\mathfrak{m}(I + \mathfrak{m}^r)}\right) \\ &= \ell_R\left(\frac{I + \mathfrak{m}^r}{I + \mathfrak{m}^{r+1}}\right) + \ell_R\left(\frac{I + \mathfrak{m}^{r+1}}{\mathfrak{m}I + \mathfrak{m}^{r+1}}\right). \end{aligned}$$

But

$$\begin{aligned} I/\mathfrak{m}I &= \frac{I}{\mathfrak{m}I + (I \cap \mathfrak{m}^{r+1})} \\ &= \frac{I}{I \cap (\mathfrak{m}I + \mathfrak{m}^{r+1})} \\ &\cong \frac{I + \mathfrak{m}^{r+1}}{\mathfrak{m}I + \mathfrak{m}^{r+1}}. \end{aligned}$$

Putting these together we find  $e(R) \geq \mu_R(I)$  in this case as well. In fact, if we set  $\mathfrak{m}' = \mathfrak{m}/I$ , the maximal ideal of  $R/I$ , then we have

$$\frac{I + \mathfrak{m}^r}{I + \mathfrak{m}^{r+1}} \cong \mathfrak{m}'^r / \mathfrak{m}'^{r+1},$$

which for large  $r$  has length equal to  $e(R/I)$  by (i). This gives  $\mu_R(I) \leq e(R) - e(R/I)$ . (This argument is due to Kirby [Kir75]).

The bound in (ii) is sharp by (i). Every finite birational extension of  $R$  is isomorphic as an  $R$ -module to an ideal of  $R$  (clear denominators), and is therefore generated by at most  $e(R)$  elements. Proposition 4.4 shows that the bound is sharp.

For (iv) we observe that  $\bar{R}$  is a principal ideal ring, so there exists a nonzerodivisor  $x \in R$  such that  $\mathfrak{m}\bar{R} = x\bar{R}$ . Thus  $\mu_R(\bar{R}) = \ell_R(\bar{R}/\mathfrak{m}\bar{R}) = \ell_R(\bar{R}/x\bar{R})$ . By Theorem A.25 and Proposition A.21 this is equal to  $e_R((x), \bar{R}) = e_R(\mathfrak{m}, \bar{R})$ . Since  $\bar{R}$  is a birational extension of  $R$ , it has constant rank 1, so  $e_R(\mathfrak{m}, \bar{R}) = e(R)$  by Proposition A.29.  $\square$

### §3 Henselian rings

We gather here a few equivalent conditions for a local ring to be Henselian. Condition (v) is the definition used in Chapter 1; condition (i) is one of the classical formulations.

**A.31 Theorem.** *Let  $(R, \mathfrak{m}, k)$  be a local ring. These are equivalent.*

- (i) *For every monic polynomial  $f$  in  $R[x]$  and every factorization  $\bar{f} = g_0 h_0$  of its image in  $k[x]$ , where  $g_0$  and  $h_0$  are relatively prime monic polynomials, there exist monic polynomials  $g, h \in R[x]$  such that  $g \equiv g_0 \pmod{\mathfrak{m}}$ ,  $h \equiv h_0 \pmod{\mathfrak{m}}$ , and  $f = gh$ .*
- (ii) *Every commutative module-finite  $R$ -algebra which is an integral domain is local.*
- (iii) *Every commutative module-finite  $R$ -algebra is a direct product of local rings.*
- (iv) *Every module-finite  $R$ -algebra of the form  $R[x]/(f)$ , where  $f$  is a monic polynomial, is a direct product of local rings.*
- (v) *For every module-finite  $R$ -algebra  $\Lambda$  (not necessarily commutative) with Jacobson radical  $\mathcal{J}(\Lambda)$ , each idempotent of  $\Lambda/\mathcal{J}(\Lambda)$  lifts to an idempotent of  $\Lambda$ .*

*Proof.* We prove (i)  $\implies$  (ii)  $\implies$  (iii)  $\implies$  (v)  $\implies$  (iv)  $\implies$  (i).

(i)  $\implies$  (ii): Let  $D$  be a domain that is module-finite over  $R$ , and suppose  $D$  is not local. Then there exist non-units  $\alpha$  and  $\beta$  of  $D$  such that  $\alpha + \beta = 1$ . Set  $S = R[\alpha] \subseteq D$ ; then  $\alpha$  and  $\beta$  are still non-units of  $S$ . Since in particular they are not in  $\mathfrak{m}S$  by Lemma 1.7, it follows that  $S/\mathfrak{m}S = k[\bar{\alpha}]$  is a non-local finite-dimensional  $k$ -algebra. Thus the minimal polynomial  $p(x) \in k[x]$  for  $\bar{\alpha}$  is not just a power of a single irreducible polynomial. Let  $f \in R[x]$  be a monic polynomial of least degree with  $f(\alpha) = 0$ . Then  $p$  divides  $\bar{f} \in k[x]$ , so that the irreducible factorization of  $\bar{f}$  involves at least two distinct monic

irreducible factors. Therefore we may write  $\bar{f} = g_0 h_0$ , where  $g_0$  and  $h_0$  are monic polynomials of positive degree satisfying  $\gcd(g_0, h_0) = 1$ . Lifting this factorization to  $R[x]$ , we have  $f = gh$ . By the minimality of  $\deg f$ , we have  $g(\alpha) \neq 0 \neq h(\alpha)$ , but  $g(\alpha)h(\alpha) = f(\alpha) = 0$  in  $D$ , a contradiction.

(ii)  $\implies$  (iii): Let  $S$  be a commutative, module-finite  $R$ -algebra. Then  $S$  is semilocal, say with maximal ideals  $\mathfrak{m}_1, \dots, \mathfrak{m}_t$ . Set  $X_i = \{\mathfrak{p} \in \text{Spec } S \mid \mathfrak{p} \subseteq \mathfrak{m}_i\}$  for  $i = 1, \dots, t$ . By applying (ii) to each of the domains  $S/\mathfrak{p}$ , as  $\mathfrak{p}$  runs over  $\text{Spec}(S)$ , we see that the sets  $X_i$  are pairwise disjoint. Moreover, letting  $\mathfrak{p}_{ij}$ ,  $j = 1, \dots, s_i$ , be the minimal prime ideals contained in each  $\mathfrak{m}_i$ , we see that  $X_i = V(\mathfrak{p}_{i1}) \cup \dots \cup V(\mathfrak{p}_{is_i})$ , a closed set. Thus  $\text{Spec}(S)$  is a disjoint union of open-and-closed sets, and (iii) follows.

(iii)  $\implies$  (v): Let  $\Lambda$  be a module-finite  $R$ -algebra, not necessarily commutative, and let  $e \in \Lambda/\mathcal{J}(\Lambda)$  satisfy  $e^2 = e$ . Let  $\alpha \in \Lambda$  be any lifting of  $e$ , and set  $S = R[\alpha]$ . One checks that  $\mathcal{J}(S) = S \cap \mathcal{J}(\Lambda)$ , so that  $\alpha^2 - \alpha \in \mathcal{J}(S)$ . As  $S$  is a direct product of local rings, the same is true of  $S/\mathcal{J}(S)$ . The idempotent  $\bar{\alpha} \in S/\mathcal{J}(S)$  is therefore a sum of some subset of the primitive idempotents of  $S/\mathcal{J}(S)$ . Each of these primitive idempotents clearly lifts to  $S$ , so  $\alpha$  lifts to an idempotent of  $S$ , which lifts  $e$  as well.

(v)  $\implies$  (iv): Suppose  $S = R[x]/(f)$  with  $f$  a monic polynomial. Then  $S/\mathfrak{m}S = k[x]/(\bar{f})$  is a direct product of local finite-dimensional  $k$ -algebras. Since  $\mathfrak{m}S \subseteq \mathcal{J}(S)$  by Lemma 1.7, we have  $S/\mathfrak{m}S \twoheadrightarrow S/\mathcal{J}(S)$ , so  $S/\mathcal{J}(S) \cong \bar{T}_1 \times \dots \times \bar{T}_n$  is also a direct product of local rings  $\bar{T}_i$ . The primitive idempotents of this decomposition lift to idempotents  $e_1, \dots, e_n$  of  $S$ , giving a decomposition  $S = T_1 \times \dots \times T_n$  with  $T_i = e_i S$ . Since each  $\bar{T}_i = T_i/\mathcal{J}(S)T_i$  is local so is each  $T_i$ .

(iv)  $\implies$  (i): Let  $f \in R[x]$  be monic and let  $\bar{f} = g_0 h_0$  be a factorization of the image  $\bar{f} \in k[x]$  into relatively prime monic polynomials. Set  $S = R[x]/(f)$ , a direct product  $S_1 \times \cdots \times S_n$  of local rings by assumption. Then  $S/\mathfrak{m}S = k[x]/(\bar{f}) \cong k[x]/(g_0) \times k[x]/(h_0)$  by the Chinese Remainder Theorem, and also  $S/\mathfrak{m}S = S_1/\mathfrak{m}S_1 \times \cdots \times S_n/\mathfrak{m}S_n$ . After reordering the factors  $S_i$  if necessary, we may assume that  $k[x]/(g_0) = S_1/\mathfrak{m}S_1 \times \cdots \times S_l/\mathfrak{m}S_l$  and  $k[x]/(h_0) = S_{l+1}/\mathfrak{m}S_{l+1} \times \cdots \times S_n/\mathfrak{m}S_n$  for some  $l$  with  $1 < l < n$ . Set  $A = S_1 \times \cdots \times S_l$ , a free  $R$ -module of rank  $\deg g_0$ . Let  $t \in A$  denote the image of  $x \in S$ , and let  $g \in R[T]$  be the characteristic polynomial of the  $R$ -linear operator  $A \rightarrow A$  given by multiplication by  $t$ . Note that  $\bar{g} = g_0$  in  $k[x]$ . Now  $g(t) = 0$  by the Cayley-Hamilton theorem, so we have a surjective homomorphism  $R[x]/(g) \rightarrow A$ , which is in fact an isomorphism by NAK. The map  $R[x] \rightarrow A$  factors through  $S$  by construction, so we may write  $f = gh$  for some monic  $h \in R[x]$ .  $\square$

**A.32 Corollary.** *Let  $R$  be a Henselian local ring, let  $\alpha \in R$  be a unit, and let  $n$  be a positive integer prime to  $\text{char}(k)$ . If  $\bar{\alpha}$  has an  $n^{\text{th}}$  root in  $k$ , then  $\alpha$  has an  $n^{\text{th}}$  root in  $R$ .*

*Proof.* Let  $f = x^n - \alpha \in R[x]$ , and let  $\beta$  be a root of  $x^n - \bar{\alpha} \in k[x]$ . Write  $x^n - \bar{\alpha} = (x - \beta)h(x)$ . The hypotheses imply that  $x^n - \bar{\alpha}$  has  $n$  distinct roots, so  $x - \beta$  and  $h(x)$  are relatively prime. Since  $R$  is Henselian, we get  $\tilde{\beta} \in R^\times$  and  $\tilde{h} \in R[x]$  such that  $x^n - \alpha = (x - \tilde{\beta})\tilde{h}$ . Then  $\tilde{\beta}^n = \alpha$ .  $\square$

**A.33 Remark.** For completeness we mention a few more equivalent conditions. The proof of these equivalences is beyond our scope. Let  $(R, \mathfrak{m}, k)$  be a local ring. Recall (Definition 10.2) that a *pointed étale neighborhood* of  $R$

is a flat local  $R$ -algebra  $(S, \mathfrak{n})$ , essentially of finite type, such that  $\mathfrak{m}S = \mathfrak{n}$  and  $S/\mathfrak{n} = k$ . There is a structure theory for such extensions [Ive73, III.2]:  $S$  is a pointed étale neighborhood of  $R$  if and only if  $S \cong (R[x]/(f))_{\mathfrak{p}}$ , where  $f$  is a monic polynomial,  $\mathfrak{p}$  is a maximal ideal of  $R[x]/(f)$  satisfying  $f' \notin \mathfrak{p}$ , and  $S/\mathfrak{p}S = R/\mathfrak{m}$ .

The following conditions are then equivalent to those of Theorem A.31.

- (v) *If  $R \rightarrow S$  is a pointed étale neighborhood, then  $R \cong S$ .*
- (vi) *For every monic polynomial  $f \in R[x]$  and every  $\alpha \in R$  such that  $f(\alpha) \in \mathfrak{m}$  and  $f'(\alpha) \notin \mathfrak{m}$ , there exists  $r \in R$  such that  $r \equiv \alpha \pmod{\mathfrak{m}}$  and  $f(r) = 0$ .*
- (vii) *For every system of polynomials  $f_1, \dots, f_n \in R[x_1, \dots, x_n]$  and every  $(\alpha_1, \dots, \alpha_n) \in R^{(n)}$  such that  $f_i(\alpha_1, \dots, \alpha_n) \in \mathfrak{m}$  and the Jacobian determinant  $\det \left[ \frac{\partial f_i}{\partial x_j}(\alpha_1, \dots, \alpha_n) \right]$  is a unit, there exist  $r_1, \dots, r_n \in R$  such that  $r_i \equiv \alpha_i \pmod{\mathfrak{m}}$  and  $f_i(r_1, \dots, r_n) = 0$  for all  $i = 1, \dots, n$ .*

Condition (vi) (“simple roots lift from  $k$  to  $R$ ”) is also sometimes used as the definition of Henselianness.

# B

## *Ramification Theory*

This appendix contains the basic results we need in the body of the text on unramified and étale ring homomorphisms, as well as the ramification behavior of prime ideals in integral extensions. We also include proofs of the theorem on the purity of the branch locus (Theorem B.12) and results relating ramification to pseudo-reflections in finite groups of linear ring automorphisms.

### §1 Unramified homomorphisms

Recall that a ring homomorphism  $A \rightarrow B$  is said to be of *finite type* if  $B$  is a finitely generated  $A$ -algebra, that is,  $B \cong A[x_1, \dots, x_n]/I$  for some polynomial variables  $x_1, \dots, x_n$  and an ideal  $I$ . We say  $A \rightarrow B$  is *essentially of finite type* if  $B$  is a localization (at an arbitrary multiplicatively closed set) of an  $A$ -algebra of finite type.

**B.1 Definition.** Let  $(A, \mathfrak{m}, k) \rightarrow (B, \mathfrak{n}, \ell)$  be a local homomorphism of local rings. We say that  $A \rightarrow B$  is an *unramified local homomorphism* provided

- (i)  $\mathfrak{m}B = \mathfrak{n}$ ,
- (ii)  $B/\mathfrak{m}B$  is a finite separable field extension of  $A/\mathfrak{m}$ , and
- (iii)  $B$  is essentially of finite type over  $A$ .

If in addition  $A \rightarrow B$  is flat, we say it is *étale*.

**B.2 Remarks.** Let  $A \rightarrow B$  be a local homomorphism of local rings. Let  $\widehat{A}$  and  $\widehat{B}$  be the  $\mathfrak{m}$ -adic and  $\mathfrak{n}$ -adic completions of  $A$  and  $B$ , respectively. It is straightforward to check that  $A \rightarrow B$  is unramified, respectively étale, if and only if  $\widehat{A} \rightarrow \widehat{B}$  is so.

If  $A \rightarrow B$  is an unramified local homomorphism, then  $\widehat{B}$  is a finitely generated  $\widehat{A}$ -module. Indeed, it follows from the complete version of NAK ([Mat89, Theorem 8.4] or [Eis95, Exercises 7.2 and 7.4]) that any  $k = \widehat{A}/\widehat{\mathfrak{m}}$ -vector space basis for  $\ell = \widehat{B}/\widehat{\mathfrak{n}}$  lifts to a set of  $\widehat{A}$ -module generators for  $\widehat{B}$ . If, in particular, there is no residue field growth (for instance, if  $k$  is separably or algebraically closed), then  $\widehat{A} \rightarrow \widehat{B}$  is surjective.

If  $A \rightarrow B$  is étale, then  $\widehat{B}$  is a finitely generated flat  $\widehat{A}$ -module, whence  $\widehat{B} \cong \widehat{A}^{(n)}$  for some  $n$ . If in this case  $k = \ell$ , then  $\widehat{B} = \widehat{A}$ .

It's easy to check that if  $A \rightarrow B$  is étale, then  $A$  and  $B$  share the same Krull dimension and the same depth. Furthermore,  $A$  is regular if and only if  $B$  is regular. For further permanence results along these lines, we need to globalize the definition.

**B.3 Definition.** Let  $A$  and  $B$  be Noetherian rings, and  $A \rightarrow B$  a homomorphism essentially of finite type. Let  $\mathfrak{q} \in \text{Spec} B$  and set  $\mathfrak{p} = A \cap \mathfrak{q}$ . We say that  $A \rightarrow B$  is *unramified at*  $\mathfrak{q}$  (or also  $\mathfrak{q}$  is *unramified over*  $A$ ) if and only if the induced map  $A_{\mathfrak{p}} \rightarrow B_{\mathfrak{q}}$  is an unramified local homomorphism of local rings. Similarly,  $A \rightarrow B$  is *étale at*  $\mathfrak{q}$  if and only if  $A_{\mathfrak{p}} \rightarrow B_{\mathfrak{q}}$  is an étale local homomorphism. Finally,  $A \rightarrow B$  is *unramified*, resp. *étale*, if it is unramified, respectively étale, at every prime ideal  $\mathfrak{q} \in \text{Spec} B$ .

Here is an easy transitivity property of unramified primes.

**B.4 Lemma.** *Let  $A \rightarrow B \rightarrow C$  be homomorphisms, essentially of finite type, of Noetherian rings. Let  $\mathfrak{v} \in \text{Spec } C$  and set  $\mathfrak{q} = B \cap \mathfrak{v}$ .*

(i) *If  $\mathfrak{v}$  is unramified over  $B$  and  $\mathfrak{q}$  is unramified over  $A$ , then  $\mathfrak{v}$  is unramified over  $A$ .*

(ii) *If  $\mathfrak{v}$  is unramified over  $A$ , then  $\mathfrak{v}$  is unramified over  $B$ .*

It is clear that a local homomorphism  $(A, \mathfrak{m}) \rightarrow (B, \mathfrak{n})$  essentially of finite type is an unramified local homomorphism if and only if  $\mathfrak{n}$  is unramified over  $A$ . However, it's not at all clear that an unramified local homomorphism is unramified in the sense of Definition B.3. To reconcile these definitions, we must show that being unramified is preserved under localization. The easiest way to do this is to give an alternative description, following [AB59].

**B.5 Definition.** Let  $A \rightarrow B$  be a homomorphism of Noetherian rings. Define the *diagonal map*  $\mu: B \otimes_A B \rightarrow B$  by  $\mu(b \otimes b') = bb'$  for all  $b, b' \in B$ , and set  $\mathcal{J} = \ker \mu$ . Thus we have a short exact sequence of  $B \otimes_A B$ -modules

$$(B.5.1) \quad 0 \longrightarrow \mathcal{J} \longrightarrow B \otimes_A B \xrightarrow{\mu} B \longrightarrow 0.$$

**B.6 Remarks.**

(i) The ideal  $\mathcal{J}$  is generated by all elements of the form  $b \otimes 1 - 1 \otimes b$ , where  $b \in B$ . Indeed, if  $\mu(\sum_j b_j \otimes b'_j) = 0$ , then  $\sum_j b_j b'_j = 0$ , so that

$$\sum_j b_j \otimes b'_j = \sum_j (1 \otimes b'_j)(b_j \otimes 1 - 1 \otimes b_j).$$

- (ii) The ring  $B \otimes_A B$ , also called the *enveloping algebra* of the  $A$ -algebra  $B$ , has two  $A$ -module structures, one on each side. Thus  $\mathcal{I}$  also has two different  $B$ -structures. However, these two module structures coincide modulo  $\mathcal{I}^2$ . The reason is that

$$\mathcal{I}/\mathcal{I}^2 = ((B \otimes_A B)/\mathcal{I}) \otimes_{B \otimes_A B} \mathcal{I}$$

is a  $(B \otimes_A B)/\mathcal{I}$ -module, and  $(B \otimes_A B)/\mathcal{I} = B$ . In particular,  $\mathcal{I}/\mathcal{I}^2$  has an unambiguous  $B$ -module structure.

- (iii) The  $B$ -module  $\mathcal{I}/\mathcal{I}^2$  is also known as the *module of (relative) Kähler differentials of  $B$  over  $A$* , denoted  $\Omega_{B/A}$  [Eis95, Chapter 16]. It is the universal module of  $A$ -linear derivations on  $B$ , in the sense that the map  $\delta: B \rightarrow \mathcal{I}/\mathcal{I}^2$  sending  $b$  to  $b \otimes 1 - 1 \otimes b$  is an  $A$ -linear derivation (satisfies the Leibniz rule), and given any  $A$ -linear derivation  $\epsilon: B \rightarrow M$ , there exists a unique  $B$ -linear homomorphism  $\mathcal{I}/\mathcal{I}^2 \rightarrow M$  making the obvious diagram commute. In particular we have  $\text{Der}_A(B, M) \cong \text{Hom}_B(\mathcal{I}/\mathcal{I}^2, M)$  for every  $B$ -module  $M$ . Though it is very important for a deeper study of unramified maps, will not need this interpretation in this book.

- (iv) If  $A \rightarrow B$  is assumed to be essentially of finite type,  $\mathcal{I}$  is a finitely generated  $B \otimes_A B$ -module. To see this, first observe that the question reduces at once to the case where  $B$  is of finite type over  $A$ . In that case, if  $x_1, \dots, x_n$  are  $A$ -algebra generators for  $B$ , one checks that the elements  $x_i \otimes 1 - 1 \otimes x_i$ , for  $i = 1, \dots, n$ , generate  $\mathcal{I}$ . It follows that if  $A \rightarrow B$  is essentially of finite type then  $\mathcal{I}/\mathcal{I}^2$  is a finitely generated  $B$ -module.

- (v) The term “diagonal map” comes from the geometry. If  $f: A \hookrightarrow B$  is an integral extension of integral domains which are finitely generated algebras over an algebraically closed field  $k$ , then there is a corresponding surjective map of irreducible varieties  $f^\#: Y \rightarrow X$ , where  $X$  is the maximal ideal spectrum of  $A$  and  $Y$  is that of  $B$ . In this case, the maximal ideal spectrum of  $B \otimes_A B$  is the fiber product

$$Y \times_X Y = \{(y_1, y_2) \in Y \times Y \mid f^\#(y_1) = f^\#(y_2)\}.$$

The map  $\mu: B \otimes_A B \rightarrow B$  corresponds to the diagonal embedding  $\mu^\#: Y \rightarrow Y \times_X Y$  taking  $y$  to  $(y, y)$ . In these terms,  $\mathcal{I}$  is the ideal of functions on  $Y \times_X Y$  vanishing on the diagonal.

**B.7 Lemma.** *Let  $A \rightarrow B$  be a homomorphism of Noetherian rings. Then the following conditions are equivalent.*

- (i)  $B$  is a projective  $B \otimes_A B$ -module.
- (ii) The exact sequence  $0 \rightarrow \mathcal{I} \rightarrow B \otimes_A B \xrightarrow{\mu} B \rightarrow 0$  splits as  $B \otimes_A B$ -modules.
- (iii)  $\mu(\text{Ann}_{B \otimes_A B}(\mathcal{I})) = B$ .

If  $\mathcal{I}/\mathcal{I}^2$  is a finitely generated  $B$ -module (for example, if  $A \rightarrow B$  is essentially of finite type), then these are equivalent to

- (iv)  $\mathcal{I}$  is generated by an idempotent.
- (v)  $\mathcal{I}/\mathcal{I}^2 = 0$ .

*Proof.* (i)  $\iff$  (ii) is clear.

(ii)  $\iff$  (iii): The map  $\mu: B \otimes_A B \rightarrow B$  splits over  $B \otimes_A B$  if and only if the induced homomorphism

$$\mathrm{Hom}_{B \otimes_A B}(B, \mu): \mathrm{Hom}_{B \otimes_A B}(B, B \otimes_A B) \rightarrow \mathrm{Hom}_{B \otimes_A B}(B, B)$$

is surjective. However, the isomorphism  $B \cong (B \otimes_A B) / \mathcal{I}$  shows that  $\mathrm{Hom}_{B \otimes_A B}(B, B \otimes_A B) \cong \mathrm{Ann}_{B \otimes_A B}(\mathcal{I})$ , so that  $\mu$  splits if and only if  $\mathrm{Hom}_{B \otimes_A B}(B, \mu)$  is surjective, if and only if  $\mu(\mathrm{Ann}_{B \otimes_A B}(\mathcal{I})) = B$ .

The final two statements are always equivalent for a finitely generated ideal. Assume (iv), so that there exists  $z \in \mathcal{I}$  with  $xz = x$  for every  $x \in \mathcal{I}$ . Define  $q: B \otimes_A B \rightarrow \mathcal{I}$  by  $q(x) = xz$ . Then for  $x \in \mathcal{I}$ , we have  $q(x) = x$ , so that the sequence splits. Conversely, any splitting  $q$  of the map  $\mathcal{I} \rightarrow B \otimes_A B$  yields an idempotent  $z = q(1)$ , so (ii) and (iv) are equivalent.  $\square$

The proof of the next result is too long for us to include here, even though it is the foundation for the theory. See [Eis95, Corollary 16.16].<sup>1</sup>

**B.8 Proposition.** *Suppose that  $A$  is a field and  $B$  is an  $A$ -algebra essentially of finite type. Then the equivalent conditions of Lemma B.7 hold if and only if  $B$  is a direct product of a finite number of fields, each finite and separable over  $A$ .*

The condition in the Proposition that  $B$  be a direct product of a finite number of fields, each finite and separable over  $A$ , is sometimes called a

<sup>1</sup>Sketch: In the special case where  $A$  and  $B$  are both fields, one can show that if  $B$  is projective over  $B \otimes_A B$  then  $A \rightarrow B$  is necessarily module-finite. Then a separability idempotent  $z \in \mathcal{I}$  is given as follows: let  $\alpha \in B$  be a primitive element, with minimal polynomial  $f(x) = (x - \alpha) \sum_{i=0}^{n-1} b_i x^i$ . Then  $z = \left(1 \otimes \frac{1}{f'(\alpha)}\right) \sum_{i=0}^{n-1} \alpha^i \otimes b_i$  is idempotent.

“(classically) separable algebra” in the literature. Equivalently,  $K \otimes_A B$  is a reduced ring for every field extension  $K$  of  $A$ .

We now relate the equivalent conditions of Lemma B.7 to the definitions at the beginning of the Appendix.

**B.9 Proposition.** *Let  $A \rightarrow B$  be a homomorphism, essentially of finite type, of Noetherian rings. The following statements are equivalent.*

- (i) *The exact sequence  $0 \rightarrow \mathcal{I} \rightarrow B \otimes_A B \xrightarrow{\mu} B \rightarrow 0$  splits as  $B \otimes_A B$ -modules.*
- (ii)  *$B$  is unramified over  $A$ .*
- (iii) *Every maximal ideal of  $B$  is unramified over  $A$ .*

*Proof.* (i)  $\implies$  (ii): Let  $\mathfrak{q} \in \text{Spec } B$ , and let  $\mathfrak{p} = A \cap \mathfrak{q}$  be its contraction to  $A$ . It is enough to show that  $B_{\mathfrak{p}}/\mathfrak{p}B_{\mathfrak{p}}$  is unramified over the field  $A_{\mathfrak{p}}/\mathfrak{p}A_{\mathfrak{p}}$ , i.e. is a finite direct product of finite separable field extensions. By Proposition B.8, it suffices to show that  $B_{\mathfrak{p}}/\mathfrak{p}B_{\mathfrak{p}}$  is a projective module over  $B_{\mathfrak{p}}/\mathfrak{p}B_{\mathfrak{p}} \otimes_{A_{\mathfrak{p}}/\mathfrak{p}A_{\mathfrak{p}}} B_{\mathfrak{p}}/\mathfrak{p}B_{\mathfrak{p}}$ . Let  $p: B \rightarrow B \otimes_A B$  be a splitting for  $\mu$ , so that  $\mu p = 1_B$ . Set  $y = p(1)$ . Then  $\mu(y) = 1$  and  $y \in \ker \mu = 0$ ; in fact, the existence of an element  $y$  satisfying these two conditions is easily seen to be equivalent to the existence of a splitting of  $\mu$ . Consider the diagram

$$\begin{array}{ccccc}
 B \otimes_A B & \xrightarrow{f} & B_{\mathfrak{p}} \otimes_{A_{\mathfrak{p}}} B_{\mathfrak{p}} & \xrightarrow{g} & B_{\mathfrak{p}}/\mathfrak{p}B_{\mathfrak{p}} \otimes_{A_{\mathfrak{p}}} B_{\mathfrak{p}}/\mathfrak{p}B_{\mathfrak{p}} \\
 \mu \downarrow & & \downarrow \mu' & & \downarrow \mu'' \\
 B & \longrightarrow & B_{\mathfrak{p}} & \longrightarrow & B_{\mathfrak{p}}/\mathfrak{p}B_{\mathfrak{p}}
 \end{array}$$

in which the horizontal arrows are the natural ones and the vertical arrows are the respective diagonal maps. Put  $y'' = gf(y)$ . Then  $\mu''(y'') =$

1 and  $y \ker(\mu'') = 0$ , so that  $\mu''$  splits. Since the top-right ring is also  $B_{\mathfrak{p}}/\mathfrak{p}B_{\mathfrak{p}} \otimes_{A_{\mathfrak{p}}/\mathfrak{p}A_{\mathfrak{p}}} B_{\mathfrak{p}}/\mathfrak{p}B_{\mathfrak{p}}$ , this shows that  $A_{\mathfrak{p}}/\mathfrak{p}A_{\mathfrak{p}} \rightarrow B_{\mathfrak{p}}/\mathfrak{p}B_{\mathfrak{p}}$  is unramified.

(ii)  $\implies$  (iii) is obvious.

(iii)  $\implies$  (i): Since  $\mathcal{J}$  is a finitely generated  $B$ -module, it suffices to assume that  $A \rightarrow B$  is an unramified local homomorphism of local rings and show that  $\mathcal{J} = \mathcal{J}^2$ . Once again we reduce to the case where  $A$  is a field and  $B$  is a separable  $A$ -algebra. In this case Proposition B.8 implies that  $\mathcal{J} = \mathcal{J}^2$ .  $\square$

**B.10 Remarks.** This proposition reconciles the two definitions of unramifiedness given at the beginning of the Appendix, since it implies that unramifiedness is preserved by localization. This has some very satisfactory consequences. One can now use the characterizations of reducedness and normality in terms of the conditions  $(R_n)$  and  $(S_n)$  to see that if  $A \rightarrow B$  is étale, then  $A$  is reduced, resp. normal, if and only if  $B$  is so. Note that this fact would be *false* without the hypothesis that  $A \rightarrow B$  is essentially of finite type. Indeed, the natural completion homomorphism  $A \rightarrow \widehat{A}$  satisfies (i) and (ii) of Definition B.1, and is of course flat, but there are examples of completion not preserving reducedness or normality.

Proposition B.9 also allows us to expand our use of language, saying that a prime ideal  $\mathfrak{p} \in \text{Spec } A$  is *unramified in  $B$*  if the localization  $A_{\mathfrak{p}} \rightarrow B_{\mathfrak{p}}$  is unramified, that is, every prime ideal of  $B$  lying over  $\mathfrak{p}$  is unramified.

We now define the *homological different* of the  $A$ -algebra  $B$ , which will be used several times in the text. It is the ideal of  $B$

$$\mathfrak{H}_A(B) = \mu(\text{Ann}_{B \otimes_A B}(\mathcal{J})),$$

where  $\mu: B \otimes_A B \rightarrow B$  is the diagonal. The homological different defines the *branch locus* of  $A \rightarrow B$ , that is, the primes of  $B$  which are ramified over  $A$ , as we now show.

**B.11 Theorem.** *Let  $A \rightarrow B$  be a homomorphism, essentially of finite type, of Noetherian rings. A prime ideal  $\mathfrak{q} \in \text{Spec} B$  is unramified over  $A$  if and only if  $\mathfrak{q}$  does not contain  $\mathfrak{h}_A(B)$ .*

*Proof.* This follows from Proposition B.9 and condition (iii) of Lemma B.7, together with the observation that formation of  $\mathcal{J}$  commutes with localization at  $\mathfrak{q}$  and  $A \cap \mathfrak{q}$ . Precisely, let  $\mathfrak{q} \in \text{Spec} B$  and set  $\mathfrak{p} = A \cap \mathfrak{q}$ . Let  $S$  be the multiplicatively closed set of simple tensors  $u \otimes v$ , where  $u$  and  $v$  range over  $B \setminus \mathfrak{q}$ . Then  $(B \otimes_A B)_S \cong B_{\mathfrak{q}} \otimes_A B_{\mathfrak{q}} \cong B_{\mathfrak{q}} \otimes_{A_{\mathfrak{p}}} B_{\mathfrak{q}}$  and the kernel of the map  $\tilde{\mu}: B_{\mathfrak{q}} \otimes_{A_{\mathfrak{p}}} B_{\mathfrak{q}} \rightarrow B_{\mathfrak{q}}$  coincides with  $(\ker \mu)_S$ .  $\square$

## §2 Purity of the branch locus

Turn now to the theorem on the purity of the branch locus. The proof we give, following Auslander–Buchsbaum [AB59] and Auslander [Aus62], is somewhat lengthy.

For the rest of this Appendix, we will be mainly concerned with finite integral extensions  $A \rightarrow B$  of Noetherian domains. In particular they will be of finite type. Recall that for a finite integral extension, we have the “lying over” and “going up” properties; if in addition  $A$  is normal, then we also have “going down” [Mat89, Theorems 9.3 and 9.4]. In particular, in this case we have  $\text{height } \mathfrak{q} = \text{height}(A \cap \mathfrak{q})$  for  $\mathfrak{q} \in \text{Spec} B$  ([Mat89, 9.8, 9.9]).

Recall also that since a normal domain satisfies Serre's condition  $(S_2)$ , the associated primes of a principal ideal all have height one (see [Eis95, Theorem 11.5]). In other words, principal ideals have pure height one.

**B.12 Theorem** (Purity of the branch locus). *Let  $A$  be a regular ring and  $A \hookrightarrow B$  a module-finite ring extension with  $B$  normal. Then  $\mathcal{S}_A(B)$  is an ideal of pure codimension one in  $B$ . In particular, if  $A \rightarrow B$  is unramified in codimension one, then  $A \rightarrow B$  is unramified.*

First we observe that the condition “unramified in codimension one” can be interpreted in terms of the sequence (B.5.1).

Assume  $A \rightarrow B$  is a module-finite extension of Noetherian normal domains. We write  $B \cdot B$  for  $(B \otimes_A B)^{**}$ , where  $-^* = \text{Hom}_B(-, B)$  (see Chapter 6). Since the  $B$ -module  $B$  is reflexive, and any homomorphism from  $B \otimes_A B$  to a reflexive  $B$ -module factors through  $B \cdot B$ , we see that  $\mu: B \otimes_A B \rightarrow B$  factors as  $B \otimes_A B \rightarrow B \cdot B \xrightarrow{\mu^{**}} B$ .

**B.13 Proposition.** *A module-finite extension of Noetherian normal domains  $A \rightarrow B$  is unramified in codimension one if and only if  $\mu^{**}$  is a split surjection of  $B \otimes_A B$ -modules.*

*Proof.* If  $\mu^{**}$  is a split surjection, then  $\mu_{\mathfrak{p}}^{**}$  is a split surjection for all primes  $\mathfrak{q}$  of height one in  $B$ . For these primes, however,  $\mu_{\mathfrak{q}}^{**} = \mu_{\mathfrak{q}}$  since  $B_{\mathfrak{q}} \otimes_{A_{\mathfrak{p}}} B_{\mathfrak{q}} = (B \otimes_A B)_{\mathfrak{q}}$  is a reflexive module over the DVR  $B_{\mathfrak{q}}$ , where  $\mathfrak{p} = A \cap \mathfrak{q}$ . Thus  $\mu$  splits locally at every height-one prime of  $B$ , so  $A \rightarrow B$  is unramified in codimension one.

Now assume  $A \rightarrow B$  is unramified in codimension one. Let  $K$  be the quotient field of  $A$  and  $L$  the quotient field of  $B$ . Since  $A \rightarrow B$  is unramified

at the zero ideal,  $K \rightarrow L$  is unramified, equivalently, a finite separable field extension. In particular, the diagonal map  $\eta: L \otimes_K L \rightarrow L$  is a split epimorphism of  $L \otimes_K L$ -modules.

Since  $B \cdot B$  is  $B$ -reflexive, it is in particular torsion-free, and so  $B \cdot B$  is a submodule of  $L \otimes_K L$ . We therefore have a commutative diagram of short exact sequences

$$\begin{array}{ccccccc}
 0 & \longrightarrow & \mathcal{L} & \longrightarrow & L \otimes_K L & \xrightarrow{\eta} & L \longrightarrow 0 \\
 & & \uparrow & & \uparrow & & \uparrow \\
 0 & \longrightarrow & \mathcal{L}' & \longrightarrow & B \cdot B & \xrightarrow{\mu^{**}} & B \longrightarrow 0 \\
 & & \uparrow & & \uparrow & & \parallel \\
 0 & \longrightarrow & \mathcal{L} & \longrightarrow & B \otimes_A B & \xrightarrow{\mu} & B \longrightarrow 0
 \end{array}$$

in which the left-hand modules are by definition the kernels, and in which the top row splits over  $L \otimes_K L$  since  $L/K$  is separable. Let  $\epsilon: L \rightarrow L \otimes_K L$  be a splitting, and let  $\zeta$  be the restriction of  $\epsilon$  to  $B$ . It will suffice to show that  $\zeta(B) \subseteq B \cdot B$ , for then  $\zeta$  will be the splitting of  $\mu^{**}$  we need. For a height-one prime ideal  $\mathfrak{q}$  of  $B$ , with  $\mathfrak{p} = A \cap \mathfrak{q}$ , we do have  $\zeta_{\mathfrak{q}}(B_{\mathfrak{q}}) \subseteq (B_{\mathfrak{q}} \otimes_{A_{\mathfrak{p}}} B_{\mathfrak{q}})^{**} = (B \otimes_A B)_{\mathfrak{q}}$ , since  $A \rightarrow B$  is unramified in codimension one. But  $\text{im}(\zeta) = \bigcap_{\text{height } \mathfrak{q}=1} \text{im}(\zeta_{\mathfrak{q}})$  and  $B = \bigcap_{\text{height } \mathfrak{q}=1} B_{\mathfrak{q}}$  as  $B$  is normal, so the image of  $\zeta$  is contained in  $B \cdot B$  and  $\zeta$  is a splitting for  $\mu^{**}$ .  $\square$

Following Auslander and Buchsbaum, we shall first prove Theorem B.12 in the special case where  $B$  is a finitely generated projective  $A$ -module. In this case the homological different coincides with the Dedekind different from number theory, which we describe now.

Let  $A \rightarrow B$  be a module-finite extension of normal domains. Let  $K$  and  $L$  be the quotient fields of  $A$  and  $B$ , respectively. We assume that  $K \rightarrow L$

is a separable extension. (In the situation of Theorem B.12, this follows from the hypothesis.) In this case the trace form  $(x, y) \mapsto \text{Tr}_{L/K}(xy)$  is a non-degenerate pairing  $L \otimes_K L \rightarrow L$ , and since  $A \rightarrow B$  is integral and  $A$  is integrally closed in  $K$  we have  $\text{Tr}_{L/K}(B) \subseteq A$ . Set

$$\mathfrak{C}_A(B) = \{x \in L \mid \text{Tr}_{L/K}(xB) \subseteq A\},$$

and call it the *Dedekind complementary module for  $B/A$* . It is a fractional ideal of  $B$ .

We set  $\mathfrak{D}_A(B) = (\mathfrak{C}_A(B))^{-1}$ , the inverse of the fractional ideal  $\mathfrak{C}_A(B)$ . This is the *Dedekind different* of  $B/A$ . Since  $B \subseteq \mathfrak{C}_A(B)$ , we have  $\mathfrak{D}_A(B) \subseteq B$  and  $\mathfrak{D}_A(B)$  is an ideal of  $B$ . It is even a reflexive ideal since it is the inverse of a fractional ideal.

The following theorem is attributed to Noether ([Noe50], posthumous) and Auslander and Buchsbaum.

**B.14 Theorem.** *Let  $A \rightarrow B$  be a module-finite extension of Noetherian normal domains which induces a separable extension of quotient fields. We have  $\mathfrak{S}_A(B) \subseteq \mathfrak{D}_A(B)$ , and if  $B$  is projective as an  $A$ -module then  $\mathfrak{S}_A(B) = \mathfrak{D}_A(B)$ .*

*Proof.* Let  $K$  and  $L$  be the respective quotient fields of  $A$  and  $B$  as in the discussion above. Set  $L^* = \text{Hom}_K(L, K)$  and  $B^* = \text{Hom}_A(B, A)$ . Define

$$\sigma_L: L \otimes_K L \rightarrow \text{Hom}_L(L^*, L)$$

by  $\sigma_L(x \otimes y)(f) = xf(y)$ . Then  $\sigma_L$  restricts to  $\sigma_B: B \otimes_A B \rightarrow \text{Hom}_B(B^*, B)$ , defined similarly. It's straightforward to show that  $\sigma_B$  is an isomorphism if  $B$  is projective over  $A$ ; in particular,  $\sigma_L$  is an isomorphism. Its inverse is

defined by  $(\sigma_L)^{-1}(f) = \sum_j f(x_j^*) \otimes x_j$ , where  $\{x_j\}$  and  $\{x_j^*\}$  are dual bases for  $L$  and  $L^*$  over  $K$ .

Consider the diagram

$$\begin{array}{ccccccc} \mathrm{Hom}_B(B^*, B) & \xrightarrow{i_B} & \mathrm{Hom}_A(B^*, B) & \xleftarrow{\sigma_B} & B \otimes_A B & \xrightarrow{\mu_B} & B \\ \downarrow & & \downarrow & & \downarrow & & \downarrow \\ \mathrm{Hom}_L(L^*, L) & \xrightarrow{i_L} & \mathrm{Hom}_K(L^*, L) & \xleftarrow[\cong]{\sigma_L} & L \otimes_K L & \xrightarrow{\mu_L} & L \end{array}$$

in which  $\mu_B$  and  $\mu_L$  are the respective diagonal maps,  $i_B$  and  $i_L$  are inclusions, and the vertical arrows are all induced from the inclusion of  $B$  into  $L$ . Now  $\mathrm{Tr}_{L/K}(x) = \sum_j x_j^*(xx_j)$ , so if  $f \in \mathrm{Hom}_L(L^*, L)$  then we have  $f(\mathrm{Tr}_{L/K}) = \sum_j x_j f(x_j^*)$ . Thus the composition of the entire bottom row, left to right, is given by

$$\mu_L(\sigma_L)^{-1} i_L(f) = \mu_L \left( \sum_j f(x_j^*) \otimes x_j \right) = \sum_j f(x_j^*) x_j = f(\mathrm{Tr}_{L/K}).$$

It follows that the image of  $\mathrm{Hom}_B(B^*, B)$  in  $L$  is  $\mathcal{D}_A(B)$ .

The module  $\mathrm{Hom}_A(B^*, B)$  is naturally a  $B \otimes_A B$ -module via  $((b \otimes b')(f))(g) = bf(g \circ b')$ , where the  $b'$  on the right represents the map on  $B$  given by multiplication by that element. Thus  $\sigma_B$  is a  $B \otimes_A B$ -module homomorphism. An element  $\mathrm{Hom}_A(B^*, B)$  is in the image of  $i_B$  if and only if it is a  $B$ -module homomorphism, i.e.  $(b \otimes 1)(f) = (1 \otimes b)(f)$  for every  $b \in B$ . This is exactly saying that  $f$  annihilates  $\mathcal{I} = \ker \mu_B$ . Thus implies that  $\sigma_B(\mathrm{Ann}_{B \otimes_A B}(\mathcal{I})) \subseteq \mathrm{im} i_B$ . It follows that  $\mathfrak{H}_A(B) = \mu_B(\mathrm{Ann}_{B \otimes_A B}(\mathcal{I})) \subseteq \mathcal{D}_A(B)$ .

Finally, if  $B$  is projective as an  $A$ -module then  $\sigma_B$  is an isomorphism and  $\sigma_B(\mathrm{Ann}_{B \otimes_A B}(\mathcal{I}))$  is equal to the image of  $i_B$ . Thus  $\mathfrak{H}_A(B) = \mathcal{D}_A(B)$ .  $\square$

Next we show that  $\mathcal{D}_A(B)$  has pure height one, so in case they are equal  $\mathfrak{H}_A(B)$  does as well. We need a general fact about modules over normal domains.

**B.15 Proposition.** *Let  $A$  be a Noetherian normal domain. Let*

$$0 \longrightarrow M \longrightarrow N \longrightarrow T \longrightarrow 0$$

*be a short exact sequence of non-zero finitely generated  $A$ -modules wherein  $M$  is reflexive and  $T$  is torsion. Then  $\text{Ann}_A(T)$  is an ideal of pure height one in  $A$ .*

*Proof.* This is similar to Lemma 5.11. Let  $\mathfrak{p}$  be a prime ideal minimal over the annihilator of  $T$ . Then in particular  $\mathfrak{p}$  is an associated prime of  $T$ , so that  $\text{depth } T_{\mathfrak{p}} = 0$ . Since  $M$  is reflexive, it satisfies  $(S_2)$ , so that if  $\mathfrak{p}$  has height two or more then  $\mathfrak{M}_{\mathfrak{p}}$  has depth at least two. This contradicts the Depth Lemma. □

**B.16 Corollary.** *Let  $A \longrightarrow B$  be a module-finite extension of normal domains. Assume that the induced extension of quotient fields is separable. If  $\mathcal{D}_A(B) \neq B$ , then  $\mathcal{D}_A(B)$  is an ideal of pure height one in  $B$ . Consequently,  $\mathcal{D}_A(B) = B$  if and only if  $A \longrightarrow B$  is unramified in codimension one.*

*Proof.* For the first statement, take  $M = A$  and  $N = \mathcal{C}_A(B)$  in Proposition B.15. In the second statement, necessity follows from  $\mathfrak{H}_A(B) \subseteq \mathcal{D}_A(B)$  and Theorem B.11. Conversely, suppose  $\mathcal{D}_A(B) = B$ . Let  $\mathfrak{q}$  be a height-one prime of  $B$  and set  $\mathfrak{p} = A \cap \mathfrak{q}$ . Then  $A_{\mathfrak{p}}$  is a DVR and  $B_{\mathfrak{p}}$  is a finitely generated torsion-free  $A_{\mathfrak{p}}$ -module, whence free. Thus  $\mathfrak{H}_{A_{\mathfrak{p}}}(B_{\mathfrak{p}}) = \mathcal{D}_{A_{\mathfrak{p}}}(B_{\mathfrak{p}}) =$

$(\mathcal{D}_A(B))_p = B_p$ . By Theorem B.11  $B_p$  is unramified over  $A_p$ , so in particular  $q$  is unramified over  $p$ . □

**B.17 Corollary.** *If, in the setup of Corollary B.16,  $B$  is projective as an  $A$ -module, then  $A \rightarrow B$  is unramified if and only if it is unramified in codimension one.*

Now we turn to Auslander's proof of the theorem on the purity of the branch locus. The strategy is to reduce the general case to the situation of Corollary B.17 by proving a purely module-theoretic statement.

**B.18 Proposition.** *Let  $A \rightarrow B$  be a module-finite extension of Noetherian normal domains which is unramified in codimension one. Assume that  $A$  has the following property: If  $M$  is a finitely generated reflexive  $A$ -module such that  $\text{Hom}_A(M, M)$  is isomorphic to a direct sum of copies of  $M$ , then  $M$  is free. Then  $A \rightarrow B$  is unramified.*

*Proof.* Let  $K \rightarrow L$  be the extension of quotient fields induced by  $A \rightarrow B$ . Then  $L$  is a finite separable extension of  $K$ . By [Aus62, Prop. 1.1], we may assume in fact that  $K \rightarrow L$  is a Galois extension. (The proof of this result is somewhat technical, so we omit it.)

We are therefore in the situation of Theorem 5.12! Thus  $\text{Hom}_A(B, B)$  is isomorphic as a ring to the twisted group ring  $B\#G$ , where  $G = \text{Gal}(L/K)$ . As a  $B$ -module, and hence as an  $A$ -module,  $B\#G$  is isomorphic to a direct sum of copies of  $B$ . By hypothesis, then,  $B$  is a free  $A$ -module. Corollary B.17 now says that  $A \rightarrow B$  is unramified. □

Auslander's argument that regular local rings satisfy the condition of Proposition B.18 seems to be unique in the field; we know of nothing else quite like it. We begin with three preliminary results.

**B.19 Lemma.** *Let  $A$  be a Noetherian normal domain and  $M$  a finitely generated torsion-free  $A$ -module. Then  $\mathrm{Hom}_A(M, M)^* \cong \mathrm{Hom}_A(M^*, M^*)$ .*

*Proof.* We have the natural map  $\rho: M^* \otimes_A M \rightarrow \mathrm{Hom}_A(M, M)$  defined by  $\rho(f \otimes y)(x) = f(x)y$ , which is an isomorphism if and only if  $M$  is free; see Exercise 12.46. Dualizing yields  $\rho^*: \mathrm{Hom}_A(M, M)^* \rightarrow (M^* \otimes_A M)^* \cong \mathrm{Hom}_A(M^*, M^*)$  by Hom-tensor adjointness. Now  $\rho^*$  is a homomorphism between reflexive  $A$ -modules, which is an isomorphism in codimension one since  $A$  is normal and  $M$  is torsion-free. By Lemma 5.11,  $\rho^*$  is an isomorphism.  $\square$

**B.20 Lemma.** *Let  $(A, \mathfrak{m})$  be a local ring and  $f: M \rightarrow N$  a homomorphism of finitely generated  $A$ -modules. Assume that  $f_{\mathfrak{p}}: M_{\mathfrak{p}} \rightarrow N_{\mathfrak{p}}$  is an isomorphism for every non-maximal prime  $\mathfrak{p}$  of  $A$ . Then  $\mathrm{Ext}_A^i(f, A): \mathrm{Ext}_A^i(N, A) \rightarrow \mathrm{Ext}_A^i(M, A)$  is an isomorphism for  $i = 0, \dots, \mathrm{depth} A - 2$ .*

*Proof.* The kernel and cokernel of  $f$  both have finite length, so  $\mathrm{Ext}_A^i(\ker f, A) = \mathrm{Ext}_A^i(\mathrm{cok} f, A) = 0$  for  $i = 0, \dots, \mathrm{depth} A - 1$  [Mat89, Theorem 16.6]. The long exact sequence of Ext now gives the conclusion.  $\square$

**B.21 Proposition.** *Let  $(A, \mathfrak{m})$  be a local ring of depth at least 3 and let  $M$  be a reflexive  $A$ -module such that*

(i)  *$M$  is locally free on the punctured spectrum of  $A$ ; and*

(ii)  $\mathrm{pd}_A M \leq 1$ .

If  $M$  is not free, then

$$\ell(\mathrm{Ext}_A^1(\mathrm{Hom}_A(M, M), A)) > (\mathrm{rank}_A M) \ell(\mathrm{Ext}_A^1(M, A)).$$

*Proof.* Assume that  $M$  is not free. We have the natural homomorphism  $\rho_M: M^* \otimes_A M \rightarrow \mathrm{Hom}_A(M, M)$ , defined by  $\rho_M(f \otimes x)(y) = f(y)x$ , which is an isomorphism if and only if  $M$  is free; see Remark 12.5. In particular,  $\rho_M$  is locally an isomorphism on the punctured spectrum of  $A$ , so by Lemma B.20, we have

$$\mathrm{Ext}_A^1(M^* \otimes_A M, A) \cong \mathrm{Ext}_A^1(\mathrm{Hom}_A(M, M), A).$$

Next we claim that there is an injection  $\mathrm{Ext}_A^1(M, M) \hookrightarrow \mathrm{Ext}_A^1(M^* \otimes_A M, A)$ .

Let

$$(B.21.1) \quad 0 \rightarrow F_1 \rightarrow F_0 \rightarrow M \rightarrow 0$$

be a free resolution. Dualizing gives an exact sequence

$$(B.21.2) \quad 0 \rightarrow M^* \rightarrow F_0^* \rightarrow F_1^* \rightarrow \mathrm{Ext}_A^1(M, A) \rightarrow 0,$$

so that  $\mathrm{Tor}_{i-2}^A(M^*, M) = \mathrm{Tor}_i^A(\mathrm{Ext}_A^1(M, A), M) = 0$  for all  $i \geq 3$ . In particular, applying  $M^* \otimes_A -$  to (B.21.1) results in an exact sequence

$$0 \rightarrow M^* \otimes_A F_1 \rightarrow M^* \otimes_A F_0 \rightarrow M^* \otimes_A M \rightarrow 0.$$

Dualizing this yields an exact sequence

$$\mathrm{Hom}_A(M^* \otimes_A F_0, A) \xrightarrow{\eta} \mathrm{Hom}_A(M^* \otimes_A F_1, A) \rightarrow \mathrm{Ext}_A^1(M^* \otimes_A M, A).$$

But the homomorphism  $\eta$  is naturally isomorphic to the homomorphism  $\mathrm{Hom}_A(F_0, M^{**}) \rightarrow \mathrm{Hom}_A(F_1, M^{**})$ . Since  $M$  is reflexive, this implies that

the cokernel of  $\eta$  is isomorphic to  $\text{Ext}_A^1(M, M)$ , whence  $\text{Ext}_A^1(M, M) \hookrightarrow \text{Ext}_A^1(M^* \otimes_A M, A)$ , as claimed.

Next we claim that  $\text{Ext}_A^1(M, M) \cong \text{Ext}_A^1(M, A) \otimes_A M$ . This follows immediately from the commutative exact diagram

$$\begin{array}{ccccccc} F_0^* \otimes_A M & \longrightarrow & F_1^* \otimes_A M & \longrightarrow & \text{Ext}_A^1(M, A) \otimes_A M & \longrightarrow & 0 \\ \rho_{F_0}^M \downarrow & & \rho_{F_1}^M \downarrow & & \downarrow & & \\ \text{Hom}_A(F_0, M) & \longrightarrow & \text{Hom}_A(F_1, M) & \longrightarrow & \text{Ext}_A^1(M, M) & \longrightarrow & 0 \end{array}$$

in which the rows are the result of applying  $-\otimes_A M$  to (B.21.2) and  $\text{Hom}_A(-, M)$  to (B.21.1), respectively, the two vertical arrows  $\rho_{F_i}^M$  are isomorphisms since each  $F_i$  is free, and the third vertical arrow is induced by the other two.

Putting the pieces together so far, we have

$$\begin{aligned} \ell(\text{Hom}_A(\text{Ext}_A^1(M, M), A)) &= \ell(\text{Ext}_A^1(M^* \otimes_A M, A)) \\ &\geq \ell(\text{Ext}_A^1(M, M)) \\ &= \ell(\text{Ext}_A^1(M, A) \otimes_A M) \end{aligned}$$

Set  $T = \text{Ext}_A^1(M, A)$ . Then  $T \neq 0$ , since  $T = 0$  implies that  $M^*$  is free by (B.21.2), whence  $M$  is free as well, a contradiction. Then we have an exact sequence

$$0 \longrightarrow \text{Tor}_1^A(T, M) \longrightarrow T \otimes_A F_1 \longrightarrow T \otimes_A F_0 \longrightarrow T \otimes_A M \longrightarrow 0.$$

The rank of  $M$  is equal to  $\text{rank}_A F_0 - \text{rank}_A F_1$  by (B.21.1), so counting lengths shows that

$$\ell(T \otimes_A M) = (\text{rank}_A M) \ell(T) + \ell(\text{Tor}_1^A(T, M)).$$

But  $T$  is a non-zero module of finite length, so  $\text{Tor}_1^A(T, M) \neq 0$ , and the proof is complete.  $\square$

The next proposition serves as a template for Auslander’s proof of the theorem on the purity of the branch locus.

**B.22 Proposition.** *Let  $\mathcal{C}$  be a set of pairs  $(A, M)$  where  $A$  is a local ring and  $M$  is a finitely generated reflexive  $A$ -module. Assume that*

- (i)  $(A, M) \in \mathcal{C}$  implies  $(A_{\mathfrak{p}}, M_{\mathfrak{p}}) \in \mathcal{C}$  for every  $\mathfrak{p} \in \text{Spec } A$ ;
- (ii)  $(A, M) \in \mathcal{C}$  and  $\text{depth } A \leq 3$  imply that  $M$  is free; and
- (iii)  $(A, M) \in \mathcal{C}$ ,  $\text{depth } A > 3$ , and  $M$  locally free on the punctured spectrum imply that there exists a non-zero-divisor  $x$  in the maximal ideal of  $A$  such that  $(A/(x), (M/xM)^{**}) \in \mathcal{C}$ .

Then  $M$  is free over  $A$  for every  $(A, M)$  in  $\mathcal{C}$ .

*Proof.* If the statement fails, choose a witness  $(A, M) \in \mathcal{C}$  with  $M$  not  $A$ -free and  $\dim A$  minimal. By (ii),  $\text{depth } A > 3$ , so that by (iii) we can find a non-zero-divisor  $x$  in the maximal ideal of  $A$  such that  $(\bar{A}, \bar{M}^{**}) \in \mathcal{C}$ , where overlines denote passage modulo  $x$  and the duals are taken over  $\bar{A}$ . Since both  $\dim \bar{A}$  and  $\dim A_{\mathfrak{p}}$ , for  $\mathfrak{p}$  a non-maximal prime, are less than  $\dim A$ , minimality implies that  $\bar{M}^{**}$  is  $\bar{A}$ -free and  $M_{\mathfrak{p}}$  is  $A_{\mathfrak{p}}$ -free for every non-maximal  $\mathfrak{p}$ . In particular,  $\bar{M}_{\bar{\mathfrak{p}}}$  is  $\bar{A}_{\bar{\mathfrak{p}}}$ -free for every non-maximal prime  $\bar{\mathfrak{p}}$  of  $\bar{A}$ . Thus the natural homomorphism of  $\bar{A}$ -modules  $\bar{M} \rightarrow \bar{M}^{**}$  is locally an isomorphism on the punctured spectrum of  $\bar{A}$ . Lemma B.20 then implies

$$(B.22.1) \quad \text{Ext}_A^i(\bar{M}^{**}, \bar{A}) \cong \text{Ext}_A^i(\bar{M}, \bar{A})$$

for  $i = 0, \dots, \text{depth } \bar{A} - 2$ . In particular, (B.22.1) holds for  $i = 0$  and  $i = 1$  since  $\text{depth } \bar{A} - 2 = \text{depth } A - 3 > 0$ . In particular the case  $i = 1$  says  $\text{Ext}_A^1(\bar{M}, \bar{A}) = 0$  since  $\bar{M}^{**}$  is free.

Now, since  $M$  is reflexive, the non-zero-divisor  $x$  is also a non-zero-divisor on  $M$ , so standard index-shifting ([Mat89, p. 140]) gives  $\text{Ext}_A^1(M, \bar{A}) = \text{Ext}_A^1(\bar{M}, \bar{A}) = 0$ . The short exact sequence  $0 \rightarrow A \xrightarrow{x} A \rightarrow \bar{A} \rightarrow 0$  induces the long exact sequence containing

$$\text{Ext}_A^1(M, A) \xrightarrow{x} \text{Ext}_A^1(M, A) \rightarrow \text{Ext}_A^1(M, \bar{A}) = 0$$

so that  $\text{Ext}_A^1(M, A) = 0$  by NAK. In particular  $\text{Hom}_A(M, \bar{A}) \cong \bar{M}^*$  from the rest of the long exact sequence. But  $\text{Hom}_A(M, \bar{A}) = \text{Hom}_{\bar{A}}(\bar{M}, \bar{A})$  as well, so  $\bar{M}^* \cong (\bar{M})^*$ . Since  $\bar{M}$  is  $\bar{A}$ -free, this shows that  $\bar{M}^*$  is free over  $\bar{A}$ , and since  $x$  is a non-zero-divisor on  $M^*$  it follows that  $M^*$  is  $A$ -free. Thus  $M$  is  $A$ -free, which contradicts the choice of  $(A, M)$  and finishes the proof.  $\square$

**B.23 Proposition.** *Let  $\mathcal{C}$  be the set of pairs  $(A, M)$  where  $(A, \mathfrak{m}_A)$  is a regular local ring and  $M$  is a reflexive  $A$ -module satisfying  $\text{End}_A(M) \cong M^{(n)}$  for some  $n$ . Then  $\mathcal{C}$  satisfies the conditions of Proposition B.22. Thus  $M$  is free over  $A$  for every such  $(A, M)$ .*

*Proof.* The fact that  $\mathcal{C}$  satisfies (i) follows from  $\text{End}_{R_{\mathfrak{p}}}(M_{\mathfrak{p}}) \cong \text{End}_R(M)_{\mathfrak{p}}$  and the fact that regularity localizes.

For (ii), we note that reflexive modules over a regular local ring of dimension  $\leq 2$  are automatically free. Therefore  $M$  is locally free on the punctured spectrum; also, we may assume that  $\dim A = 3$ . Finally, the Auslander-Buchsbaum formula gives  $\text{pd}_A M \leq 1$ ; we want to show  $\text{pd}_A M = 0$ . Observe that  $n = \text{rank}_A(M)$  (by passing to the quotient field of  $A$ ), so  $\text{Ext}_A^1(\text{Hom}_A(M, M), A) \cong \text{Ext}_A^1(M^{(\text{rank}_A M)}, A) \cong \text{Ext}_A^1(M, A)^{(\text{rank}_A M)}$ . Thus by Proposition B.21  $M$  is free.

As for (iii), let  $(A, M) \in \mathcal{C}$  with  $\dim A > 3$  and  $M$  locally free on the punctured spectrum. Let  $x \in \mathfrak{m}_A \setminus \mathfrak{m}_A^2$  be a non-zerodivisor on  $A$ , hence on  $M$  as well since  $M$  is reflexive. Applying  $\mathrm{Hom}_A(M, -)$  to the short exact sequence  $0 \rightarrow M \xrightarrow{x} M \rightarrow \overline{M} \rightarrow 0$  gives

$$0 \rightarrow \mathrm{Hom}_A(M, M) \xrightarrow{x} \mathrm{Hom}_A(M, M) \rightarrow \mathrm{Hom}_A(M, \overline{M}) \rightarrow \mathrm{Ext}_A^1(M, M).$$

As  $\mathrm{Hom}_A(M, M) \cong M^{(n)}$ , the cokernel of the map  $\mathrm{Hom}_A(M, M) \xrightarrow{x} \mathrm{Hom}_A(M, M)$  is  $\overline{M}^{(n)}$ . This gives an exact sequence

$$0 \rightarrow \overline{M}^{(n)} \rightarrow \mathrm{Hom}_A(M, \overline{M}) \rightarrow \mathrm{Ext}_A^1(M, M).$$

The middle term of this sequence is isomorphic to  $\mathrm{Hom}_{\overline{A}}(\overline{M}, \overline{M})$ , and the rightmost term has finite length as  $M$  is locally free. Apply Lemma B.20, with  $i = 0$ , to the  $\overline{A}$ -homomorphism  $\overline{M}^{(n)} \rightarrow \mathrm{Hom}_{\overline{A}}(\overline{M}, \overline{M})$  to find that

$$\mathrm{Hom}_{\overline{A}}(\overline{M}, \overline{M})^* \cong (\overline{M}^*)^{(\mathrm{rank}_A M)},$$

whence

$$\mathrm{Hom}_{\overline{A}}(\overline{M}, \overline{M})^{**} \cong (\overline{M}^{**})^{(\mathrm{rank}_A M)}.$$

Since  $A$  is regular and  $x \notin \mathfrak{m}_A^2$ ,  $\overline{A}$  is regular as well. In particular,  $\overline{A}$  is a normal domain, so  $\mathrm{Hom}_{\overline{A}}(\overline{M}, \overline{M})^{**} = \mathrm{Hom}_{\overline{A}}(\overline{M}^{**}, \overline{M}^{**})$ . Thus  $(\overline{A}, \overline{M}^{**}) \in \mathcal{C}$ . □

**B.24 Remark.** As Auslander observes, one can use the same strategy to prove that if  $A$  is a regular local ring and  $M$  is a reflexive  $A$ -module such that  $\mathrm{End}_A(M)$  is a *free*  $A$ -module, then  $M$  is free. This is proved by other methods in [AG60], and has been extended to reflexive modules of finite projective dimension over arbitrary local rings [Bra04].

### §3 Galois extensions

Let us now investigate ramification in Galois ring extensions. We will see that ramification in codimension one is attributable to the existence of pseudo-reflections in the Galois group, and prove the Chevalley-Shephard-Todd Theorem that finite groups generated by pseudo-reflections have polynomial rings of invariants. We also prove a result due to Prill, which roughly says that for the purposes of this book we may ignore the existence of pseudo-reflections.

**B.25 Definition.** Let  $G$  be a group and  $V$  a finite-dimensional faithful representation of  $G$  over a field  $k$ . Say that  $\sigma \in G$  is a *pseudo-reflection* if  $\sigma$  has finite order and the fixed subspace  $V^\sigma = \{v \in V \mid \sigma v = v\}$  has codimension one in  $V$ . This subspace is called the *reflecting hyperplane* of  $\sigma$ .

A *reflection* is a pseudo-reflection of order 2.

If the  $V$ -action of  $\sigma \in G$  is diagonalizable, then to say  $\sigma$  is a pseudo-reflection is the same as saying  $\sigma \sim \text{diag}(1, \dots, 1, \lambda)$  where  $\lambda \neq 1$  is a root of unity. In any case, the characteristic polynomial of a pseudo-reflection has 1 as a root of multiplicity at least  $\dim V - 1$ , hence splits into a product of linear factors  $(t - 1)^{n-1}(t - \lambda)$  with  $\lambda$  a root of unity. In fact, one can show (Exercise 5.38) that a pseudo-reflection with order prime to  $\text{char}(k)$  is necessarily diagonalizable.

**B.26 Notation.** Here is the notation we will use for the rest of the Appendix. In contrast to Chapter 5, where we consider the power series case, we will work in the graded polynomial situation, since it clarifies some of the arguments. We leave the translation between the two to the

reader. Let  $k$  be a field and  $V$  an  $n$ -dimensional faithful  $k$ -representation of a finite group  $G$ , so that we may assume  $G \subseteq \mathrm{GL}(V) \cong \mathrm{GL}(n, k)$ . Set  $S = k[V] \cong k[x_1, \dots, x_n]$ , viewed as the ring of polynomial functions on  $V$ . Then  $G$  acts on  $S$  by the rule  $(\sigma f)(v) = f(\sigma^{-1}v)$ , and we set  $R = S^G$ , the subring of polynomials fixed by this action. Then  $R \rightarrow S$  is a module-finite integral extension of Noetherian normal domains. Let  $K$  and  $L$  be the quotient fields of  $R$  and  $S$ , resp.; then  $L/K$  is a Galois extension with Galois group  $G$ , and  $S$  is the integral closure of  $R$  in  $L$ . Finally, let  $\mathfrak{m}$  and  $\mathfrak{n}$  denote the obvious homogeneous maximal ideals of  $R$  and  $S$ .

**B.27 Theorem** (Chevalley-Shephard-Todd). *With notation as in B.26, consider the following conditions.*

- (i)  $R = S^G$  is a polynomial ring.
- (ii)  $S$  is free as an  $R$ -module.
- (iii)  $\mathrm{Tor}_1^R(S, k) = 0$ .
- (iv)  $G$  is generated by pseudo-reflections.

We have (i)  $\iff$  (ii)  $\iff$  (iii)  $\implies$  (iv), and all four conditions are equivalent if  $|G|$  is invertible in  $k$ .

*Proof.* (i)  $\implies$  (ii): Note that  $S$  is always a MCM  $R$ -module, so if  $R$  is a polynomial ring then  $S$  is  $R$ -free by the Auslander-Buchsbaum formula.

(ii)  $\implies$  (i): If  $S$  is free over  $R$ , then in particular it is flat. For any finitely generated  $R$ -module, then, we have  $\mathrm{Tor}_i^R(M, k) \otimes_R S = \mathrm{Tor}_i^S(S \otimes_R M, S/\mathfrak{m}S)$ . Since  $S$  is regular of dimension  $n$  and  $S/\mathfrak{m}S$  has finite length,

the latter Tor vanishes for  $i > n$ , whence the former does as well. It follows that  $R$  is regular, hence a polynomial ring.

(ii)  $\iff$  (iii): This is standard.

(i)  $\implies$  (iv): Let  $H \subseteq G$  be the subgroup of  $G$  generated by the pseudo-reflections. Then  $H$  is automatically normal. Localize the problem, setting  $A = R_{\mathfrak{m}}$ , a regular local ring by hypothesis, and  $B = (k[V]^H)_{k[V]^H \cap \mathfrak{m}}$ . Then  $A \longrightarrow B$  is a module-finite extension of local normal domains, and  $A = B^{G/H}$ .

Consider as in Chapter 5 the twisted group ring  $B\#(G/H)$ . There is, as in that chapter, a natural ring homomorphism  $\delta: B\#(G/H) \longrightarrow \text{Hom}_A(B, B)$ , which considers an element  $b\bar{\sigma} \in B\#(G/H)$  as the  $A$ -linear endomorphism  $b' \mapsto b\bar{\sigma}(b')$  of  $B$ . We claim that  $\delta$  is an isomorphism. Since source and target are reflexive over  $B$ , it suffices to check in codimension one. Let  $\mathfrak{q}$  and  $\mathfrak{p} = A \cap \mathfrak{q}$  be height-one primes of  $B$  and  $A$  respectively; then  $B_{\mathfrak{q}}$  is a finitely generated free  $A_{\mathfrak{p}}$ -module and so  $\delta_{\mathfrak{q}}: B_{\mathfrak{q}}\#(G/H) \longrightarrow \text{Hom}_{A_{\mathfrak{p}}}(B_{\mathfrak{q}}, B_{\mathfrak{q}})$  is an isomorphism. This shows that  $\delta$  is an isomorphism, and in particular  $\text{Hom}_A(B, B)$  is isomorphic as an  $A$ -module to a direct sum of copies of  $B$ . By Proposition B.23,  $B$  is free over  $A$ .

Since  $B$  is  $A$ -free, we have  $\mathfrak{H}_A(B) = \mathfrak{D}_A(B)$  by Theorem B.14. But  $\mathfrak{D}_A(B) = B$  since no non-identity element of  $G/H$  fixes a codimension-one subspace of  $V$ , i.e. a height-one prime of  $B$ . This implies  $\mathfrak{H}_A(B) = B$  so that the branch locus is empty. However, if  $G/H$  is non-trivial then  $A \longrightarrow B$  is ramified at the maximal ideal of  $B$ . Thus  $G/H = 1$ .

Finally, we prove (iv)  $\implies$  (iii) under the assumption that  $|G|$  is invertible in  $k$ . For an arbitrary finitely generated  $R$ -module  $M$ , set  $T(M) = \text{Tor}_1^R(M, k)$ . We wish to show  $T(S) = 0$ . Note that  $G$  acts naturally on  $T(S)$ ,

which is a finitely generated graded  $S$ -module.

Let  $\sigma \in G$  be a pseudo-reflection and set  $W = V^\sigma$ , a linear subspace of codimension one. Let  $f \in S$  be a linear form vanishing on  $W$ . Then  $(f)$  is a prime ideal of  $S$  of height one, and  $\sigma$  acts trivially on the quotient  $S/(f) \cong k[W]$ . For each  $g \in S$ , then, there exists a unique element  $h(g) \in S$  such that  $\sigma(g) - g = h(g)f$ . The function  $g \mapsto h(g)$  is an  $R$ -linear endomorphism of  $S$  of degree  $-1$ , with  $\sigma - 1_S = hf$  as functions on  $S$ . Applying the functor  $T(-)$  gives  $T(\sigma) - 1_{T(S)} = T(h)f_{T(S)}$  as functions on  $T(S)$ . It follows that  $\sigma(x) \equiv x \pmod{\mathfrak{n}T(S)}$  for every  $x \in T(S)$ . Since  $G$  is generated by pseudo-reflections, we conclude that  $\sigma(x) \equiv x \pmod{\mathfrak{n}T(S)}$  for every  $\sigma \in G$  and every  $x \in T(S)$ .

Next we claim that  $T(S)^G = 0$ . Define  $Q: S \rightarrow S$  by

$$Q(f) = \frac{1}{|G|} \sum_{\sigma \in G} \sigma(f),$$

so that in particular  $Q(S) = R$ . Factor  $Q$  as  $Q = iQ': S \rightarrow R \rightarrow S$ , so that  $T(Q) = T(i)T(Q')$ . Since  $T(R) = 0$ ,  $T(i)$  is the zero map, so  $T(Q) = 0$  as well. Hence

$$0 = T(Q) = \frac{1}{|G|} \sum_{\sigma \in G} T(\sigma),$$

as  $R$ -linear maps  $T(S) \rightarrow T(S)$ . But that element fixes the  $G$ -invariant elements of  $T(S)$ , so that  $T(S)^G = 0$ .

Finally, suppose  $T(S) \neq 0$ . Then there exists a homogeneous element  $x \in T(S)$  of minimal positive degree. Since  $\sigma(x) \equiv x \pmod{\mathfrak{n}T(S)}$  for every  $\sigma \in G$ ,  $x$  is an invariant of  $T(S)$ . But then  $x = 0$  as  $T(S)^G = 0$ . This completes the proof.  $\square$

It is implicit in the proof of Theorem B.27 that pseudo-reflections are responsible for ramification. Let us now bring that out into the open. Briefly, the situation is this: let  $W$  be a codimension-one subspace of  $V$ , and  $f \in S$  a linear form vanishing on  $W$ . Then  $(f)$  is a height-one prime of  $S$ , and  $(f)$  is ramified over  $R$  if and only if  $W$  is the fixed hyperplane of a pseudo-reflection.

Keep the notation in B.26, so that  $R = k[V]^G \subseteq S = k[V]$  is a module-finite extension of normal domains inducing a Galois extension of quotient fields  $K \rightarrow L$ . Since  $R \rightarrow S$  is integral, it follows from “going up” and “going down” that a prime ideal  $\mathfrak{q}$  of  $S$  has height equal to the height of  $R \cap \mathfrak{q}$ . Furthermore, for a fixed  $\mathfrak{p} \in \text{Spec} R$ , the primes  $\mathfrak{q}$  lying over  $\mathfrak{p}$  are all conjugate under the action of  $G$ . (If  $\mathfrak{q}$  and  $\mathfrak{q}'$  lying over  $\mathfrak{p}$  are not conjugate, then by “lying over” no conjugate of  $\mathfrak{q}$  contains  $\mathfrak{q}'$ . Use prime avoidance to find an element  $s \in \mathfrak{q}'$  so that  $s$  avoids all conjugates of  $\mathfrak{q}$ . Then  $\prod_{\sigma \in G} \sigma(s)$  is fixed by  $G$ , so in  $R \cap \mathfrak{q} = \mathfrak{p}$ , but not in  $\mathfrak{q}'$ .)

Assume now that  $\mathfrak{p}$  is a fixed prime of  $R$  of height one, and let  $\mathfrak{q} \subseteq S$  lie over  $\mathfrak{p}$ . Then  $R_{\mathfrak{p}} \rightarrow S_{\mathfrak{q}}$  is an extension of DVRs, so  $\mathfrak{p}S_{\mathfrak{q}} = \mathfrak{q}^e S_{\mathfrak{q}}$  for some integer  $e = e(\mathfrak{p})$ , the *ramification index* of  $\mathfrak{q}$  over  $\mathfrak{p}$ , which is independent of  $\mathfrak{q}$  by the previous paragraph. Let  $f = f(\mathfrak{p}, \mathfrak{q})$  be the *inertial degree* of  $\mathfrak{q}$  over  $\mathfrak{p}$ , i.e. the degree of the field extension  $R_{\mathfrak{p}}/\mathfrak{p}R_{\mathfrak{p}} \rightarrow S_{\mathfrak{q}}/\mathfrak{q}S_{\mathfrak{q}}$ . Then  $S_{\mathfrak{q}}/\mathfrak{p}S_{\mathfrak{q}}$  is a free  $R_{\mathfrak{p}}/\mathfrak{p}R_{\mathfrak{p}}$ -module of rank  $ef$ , so  $S_{\mathfrak{q}}$  is a free  $R_{\mathfrak{p}}$ -module of rank  $ef$ .

Let  $\mathfrak{q}_1, \dots, \mathfrak{q}_r$  be the distinct primes of  $S$  lying over  $\mathfrak{p}$ , and set  $\mathfrak{q} = \mathfrak{q}_1$ . Let  $D(\mathfrak{q})$  be the *decomposition group* of  $\mathfrak{q}$  over  $\mathfrak{p}$ ,

$$D(\mathfrak{q}) = \{\sigma \in G \mid \sigma(\mathfrak{q}) = \mathfrak{q}\}.$$

By the orbit-stabilizer theorem,  $D(\mathfrak{q})$  has index  $r$  in  $G$ . Furthermore,  $S_{\mathfrak{q}}$  is

an extension of  $R_{\mathfrak{p}}$  of rank equal to  $D(\mathfrak{q})$ , which implies  $|D(\mathfrak{q})| = ef$ .

Notice that an element of  $D(\mathfrak{q})$  induces an automorphism of  $S/\mathfrak{q}$ . We let  $T(\mathfrak{q})$ , the *inertia group* of  $\mathfrak{q}$  over  $\mathfrak{p}$ , be the subgroup inducing the identity on  $S/\mathfrak{q}$ :

$$T(\mathfrak{q}) = \{\sigma \in G \mid \sigma(f) - f \in \mathfrak{q} \text{ for all } f \in S\}.$$

Then the quotient  $D(\mathfrak{q})/T(\mathfrak{q})$  acts as Galois automorphisms of  $S_{\mathfrak{q}}/\mathfrak{q}S_{\mathfrak{q}}$  fixing  $R_{\mathfrak{p}}/\mathfrak{p}R_{\mathfrak{p}}$ . It follows that  $|D(\mathfrak{q})/T(\mathfrak{q})|$  divides the degree  $f$  of this field extension. Combining this with  $|D(\mathfrak{q})| = ef$ , we see that  $e$  divides  $|T(\mathfrak{q})|$ . In fact  $e = |T(\mathfrak{q})|$  as long as  $|G|$  is invertible in  $k$ :

**B.28 Proposition.** *Let  $\mathfrak{q}$  be a height one prime of  $S$ , set  $\mathfrak{p} = R \cap \mathfrak{q}$ , and suppose that  $T(\mathfrak{q}) \neq 1$ . Then  $\mathfrak{q} = (f)$  for some linear form  $f \in S$ . If  $W \subseteq V$  is the hyperplane on which  $f$  vanishes, then  $T(\mathfrak{q})$  is the pointwise stabilizer of  $W$ , so every non-identity element of  $T(\mathfrak{q})$  is a pseudo-reflection. Furthermore if  $|G|$  is invertible in  $k$  then  $e(\mathfrak{p}) = |T(\mathfrak{q})|$ .*

*Proof.* Since  $\mathfrak{q}$  is a prime of height one in the UFD  $S$ ,  $\mathfrak{q} = (f)$  for some homogeneous element  $f \in S$ . If  $f$  has degree 2 or more, then every linear form of  $S$  survives in  $S_{\mathfrak{q}}/\mathfrak{q}S_{\mathfrak{q}}$ , so is acted upon trivially by  $T(\mathfrak{q})$ . Since  $T(\mathfrak{q})$  is non-trivial, we must have  $\deg f = 1$ , so  $f$  is linear. The zero-set of  $f$ ,  $W = \text{Spec}S/\mathfrak{q}$ , is the subspace fixed pointwise by  $T(\mathfrak{q})$ .

For any  $\sigma \in T(\mathfrak{q})$ ,  $\sigma(f)$  vanishes on  $W$ , so  $\sigma(f) = a_{\sigma}f$  for some scalar  $a_{\sigma} \in k$ . Define a linear character  $\chi: T(\mathfrak{q}) \rightarrow k^{\times}$  by  $\chi(\sigma) = a_{\sigma}$ . The image of  $\chi$  is finite, so is cyclic of order prime to the characteristic of  $k$ . The kernel of  $\chi$  consists of the transvections in  $T(\mathfrak{q})$  (see the discussion following

Definition B.25). Since  $|G|$  is not divisible by  $p$ , the kernel of  $\chi$  is trivial, so that  $T(\mathfrak{q})$  is cyclic.

Let  $\sigma \in T(\mathfrak{q})$  be a generator, and let  $\lambda$  be the unique eigenvalue of  $\sigma$  different from 1. Then  $\lambda$  is an  $s^{\text{th}}$  root of unity for some  $s > 1$ . We can find a basis  $v_1, \dots, v_n$  for  $V$  such that  $v_1, \dots, v_{n-1}$  span  $W$ , so are fixed by  $\sigma$ , and  $\sigma v_n = \lambda v_n$ . It follows that  $k[V]^{T(\mathfrak{q})} \cong k[x_1, \dots, x_{n-1}, x_n^s]$ , and so  $\mathfrak{p} = (x_n^s)$  and  $e(\mathfrak{p}) = s = |T(\mathfrak{q})|$ .  $\square$

Recall that we say the group  $G$  is *small* if it contains no pseudo-reflections.

**B.29 Theorem.** *Let  $G \subseteq \text{GL}(V)$  be a finite group of linear automorphisms of a finite-dimensional vector space  $V$  over a field  $k$ . Set  $S = k[V]$  and  $R = S^G$ . Assume that  $|G|$  is invertible in  $k$ . Then a prime ideal  $\mathfrak{q}$  of height one in  $S$  is ramified over  $R$  if and only if  $T(\mathfrak{q}) \neq 1$ . In particular,  $R \rightarrow S$  is unramified in codimension one if and only if  $G$  is small.*

*Proof.* Let  $e = e(\mathfrak{p})$  be the ramification degree of  $\mathfrak{p} = R \cap \mathfrak{q}$ , and  $f = f(\mathfrak{p}, \mathfrak{q})$  the degree of the field extension  $R_{\mathfrak{p}}/\mathfrak{p}R_{\mathfrak{p}} \rightarrow S_{\mathfrak{q}}/\mathfrak{q}S_{\mathfrak{q}}$ . By the discussion before the Proposition,  $ef = |D(\mathfrak{q})|$ , where  $D(\mathfrak{q})$  is the decomposition group of  $\mathfrak{q}$  over  $\mathfrak{p}$ . Since the order of  $G$  is prime to the characteristic, we see that  $f$  is as well, so the field extension is separable. Therefore  $\mathfrak{q}$  is ramified over  $R$  if and only if  $e > 1$ , which occurs if and only if  $T(\mathfrak{q}) \neq 1$ .  $\square$

To close the Appendix, we record a result due to Prill [Pri67].

**B.30 Proposition.** *Let  $G$  be a finite subgroup of  $\text{GL}(V)$ , where  $V$  is an  $n$ -dimensional vector space over a field  $k$ . Set  $S = k[V]$  and  $R = S^G$ . Then there is an  $n$ -dimensional vector space  $V'$  and a small finite subgroup  $G' \subseteq \text{GL}(V')$  such that  $R \cong k[V']^{G'}$ .*

*Proof.* Let  $H$  be the normal subgroup of  $G$  generated by pseudo-reflections. By the Chevalley-Shephard-Todd theorem B.27,  $S^H$  is a polynomial ring on algebraically independent elements,  $S^H \cong k[f_1, \dots, f_n]$ . The quotient  $G/H$  acts naturally on  $S^H$ , with  $(S^H)^{G/H} = S^G$ , so it suffices to show that  $G/H$  acts on  $V' = \text{span}(f_1, \dots, f_n)$  without pseudo-reflections. Fix  $\sigma \in G \setminus H$  and let  $\tau \in H$ . Since  $\sigma\tau \notin H$ , the subspace  $V^{\sigma\tau}$  fixed by  $\sigma\tau$  has codimension at least two. The fixed locus of the action of the coset  $\sigma H$  on  $V'$  is then the intersection of  $V^{\sigma\tau}$  as  $\tau$  runs over  $H$ , so also has codimension at least two. Therefore  $\sigma H$  is not a pseudo-reflection.  $\square$

In fact the small subgroup  $G'$  of the Proposition is unique up to conjugacy in  $\text{GL}(n, k)$ . We do not prove this; see [Pri67] for a proof in the complex-analytic situation, and [DR69] for a proof in our context.
